

Additional file 6: Zinc finger DNA-binding region comparison

“Choo & Klug plot” for the C2H2 zinc finger regions of the human 8q24.3 ZNF genes and all their mammalian orthologs. For each individual zinc finger, residues -1, 3 and 6 with respect to the start of the α -helix (that were proposed to be especially important for DNA-binding specificity; see text) were extracted and consecutively written down from the N- to the C-terminal end of the whole array. For species designation see Additional file 1 or 2.

Upper case letters: Residues from canonical, complete C2H2 zinc fingers

Lower case letters: Residues from non-canonical, degenerate C2H2 zinc fingers

- separator of individual C2H2 zinc fingers

* indicates Stop codon within sequence

xxx further sequence (non C2H2 or very degenerate sequence with less than 2 out of the 4 C2H2 conserved residues at the right positions) triple x equals length of a typical C2H2 domain

gap no sequence in between but inserted to keep alignment of orthologs
