Abstract

Background: Functional loss of the tumor suppressor Smad4 is involved in pancreatic and colorectal carcinogenesis and has been associated with the acquisition of invasiveness. We have previously demonstrated that the heterotrimeric basement membrane protein laminin-332 is a Smad4 target. Namely, Smad4 functions as a positive transcriptional regulator of all three genes encoding laminin-332; its loss is thus implicated in the reduced or discontinuous deposition of the heterotrimeric basement membrane molecule as evident in carcinomas. Uncoupled expression of laminin genes, on the other hand, namely overexpression of the laminin- γ 2 chain is an impressive marker at invasive edges of carcinomas where tumor cells are maximally exposed to signals from stromal cell types like macrophages. As Smad4 is characterized as an integrator of multiple extracellular stimuli in a strongly contextual manner, we asked if loss of Smad4 may also be involved in uncoupled expression of laminin genes in response to altered environmental stimuli. Here, we address Smad4 dependent effects of the prominent inflammatory cytokine TNF α on tumor cells.

Results: Smad4-reconstituted colon carcinoma cells like adenoma cells respond to TNF α with an increased expression of all three chains encoding laminin-332; coincubation with TGF β and TNF α leads to synergistic induction and to the secretion of large amounts of the heterotrimer. In contrast, in Smad4-deficient cells TNF α can induce expression of the γ 2 and β 3 but not the α 3 chain. Surprisingly, this uncoupled induction of laminin-332 chains in Smad4-negative cells rather than causing intracellular accumulation is followed by the release of γ 2 into the medium, either in a monomeric form or in complexes with as yet unknown proteins. Soluble γ 2 is associated with increased cell migration.

Conclusions: Loss of Smad4 may lead to uncoupled induction of laminin- γ 2 in response to TNF α and may therefore represent one of the mechanisms which underlie accumulation of laminin- γ 2 at the invasive margin of a tumor. The finding, that γ 2 is secreted from tumor cells in significant amounts and is associated with increased cell migration may pave the way for further investigation to better understand its functional relevance for tumor progression.

Background

In normal tissues, the epithelium is separated from the underlying mesenchyme by the basement membrane (BM), a specialized sheet of the extracellular matrix. The BM is built from constituents produced by both the epithelial and the mesenchymal cells [1,2]. Whereas

collagen IV is the most prominent mesenchymal derived component providing the structural scaffold of the BM sheet the epithelial derived laminins build the centerpiece of the network that harbors additional proteins including perlecan, nidogen and fibulin [3]. The basement membrane has been recognized as a structural but also as an important functional component of tissues. In particular, the laminins mediate cellular functions including adhesion, migration, growth and tissue-specific gene expression [4,5].

The laminins are large heterotrimeric glycoproteins with at least 15 different isoforms composed of different combinations of one α -, one β - and one γ -chain, each, out of five α , three β and three γ -chains. The laminins are expressed in a tightly regulated development- and differentiation-specific pattern [6-8]. In the adult human intestine, laminins-211 and -511 show complementary distributions along the crypt-villus axis, whereas laminin-332 is restricted to the villus regions. In premalignant stages of colorectal carcinogenesis, namely in different types of adenomas, normal expression and deposition of laminin-332 and -511 has been reported. The transition to malignancy is defined by breaking the basement membrane barrier. In colorectal carcinomas, this is associated with a lack of laminin-511 and with irregular deposition of laminin-332 at invasive edges [9-11]. Relative overexpression of the laminin- γ 2 (and β 3) chain has often been described and represents one of the most impressive molecular markers for the invasive front of colorectal and other cancer entities (for review see [12]). It specifically marks so-called budding tumor cells [13,14]. Laminin- γ 2 has been described as a target gene of the Wnt/ β -catenin pathway [15]. Whereas β -catenin is constitutively activated through mutation of the tumor suppressor APC in the majority of adenomas the relative overexpression of γ 2 at the invasive edge of carcinomas requires additional alterations. Overexpression of γ 2 is believed to result from cellular responses to environmental signals illustrating that the regulation of laminin expression is subject to tumor cell intrinsic factors including the pattern of their respective genetic alterations and to extrinsic microenvironmental factors including signals from inflammatory cells in the tumor tissue.

We have recently identified laminin-332 as a target structure of the tumor suppressor Smad4 [16]. We have shown that Smad4 functions as a positive transcriptional regulator of all three chains encoding laminin-332. Reexpression of Smad4 led to the increased expression of heterotrimeric laminin-332 and to its deposition in basement membrane-like structures at contact sites with fibroblasts. Loss of Smad4 in the carcinogenic process, in turn, is implicated in reduced or absent expression of laminin-332 in poorly differentiated carcinomas.

Smads are primarily characterized as transmitters of signals from the TGF β superfamily of cytokines but also function as promiscuitive transcriptional coregulators that can interact with a variety of ubiquitous and tissue-specific transcription factors and coregulators in a context-dependent manner [17,18]. TGF β , in Smad4-reexpressing cancer cells like in premalignant adenoma cells induces the expression of all three genes encoding heterotrimeric laminin-332 whereas Smad4-negative cells are non-responsive [16,19]. The underlying

molecular mechanisms are surprisingly complex and involve transcription factor binding sites like AP1 which are targeted by various signaling cascades. Moreover, the modular composition of the three promoters significantly differs from each other; a functional smad binding element (SBE) is present exclusively in the LAMA3 promoter [19]. Thus, we wonder if the consequences of Smad4 loss in response to extracellular signals other than TGF β may differ between the three genes encoding laminin-332. As an approach towards modelling the cytokine environment in tumor tissues we here address effects of TNF α , a prominent inflammatory cytokine produced by tumor infiltrating macrophages, on laminin-332 expression in Smad4-positive and Smad4-deficient tumor cells.

We report, that Smad4-reexpressing human colorectal cancer cells like adenoma cells respond to TNF α with a moderate increase of all three chains encoding laminin-332 and with synergistic induction in response to the combination of TGF β and TNF α . In contrast, their Smad4-deficient counterparts display uncoupled responses to TNF α : whereas the β 3 chain and in particular the γ 2 chain is strongly induced in Smad4-negative cells, induction of the α 3 chain is Smad4-dependent and is mediated via an NF- κ B site and downstream AP1 sites in the LAMA3 promoter. Of note, TNF α induction leads to the release of significant amounts of the γ 2 chain in a monomeric form and in complex with (an) unknown protein(s) as shown by Western blotting under non-reducing conditions and confirmed by mass spectrometry. Ultimately, induced secretion of soluble γ 2 by transient suppression of the α 3 chain leads to induction of cell migration.

Results

Synergistic induction of laminin-332 in human adenoma cells in response to inflammatory cytokines TGF β and TNF α

As an approach towards modelling the microenvironment in tumor tissues we here wished to address effects of TNF α , a prominent inflammatory cytokine produced by tumor infiltrating macrophages, on laminin-332 expression of Smad4-positive and Smad4-deficient tumor cells. We use the human adenoma cell line LT97 carrying mutations of the APC and Ki-ras genes [20] as a model for early stage premalignant tumor cells with intact Smad4. We have reported previously, that LT97 cells respond to the treatment with TGF β with transcriptional induction of all three genes encoding laminin-332 [16]. Here, LT97 cells were incubated with TNF α alone or in combination with TGF β . There was no evidence for TNF α induced cell death in LT97 cells. Interestingly, whereas treatment with TNF α alone induced a moderate increase in the release of the

laminin heterotrimer, only, the combination of both cytokines led to induced secretion of laminin-332 to an enormous extent (approximately 14-fold) (Figure 1A). Western blotting under reducing conditions with laminin chain-specific antibodies confirmed that the heterotrimer is composed of the $\alpha 3$, $\beta 3$ and $\gamma 2$ chains, as expected (data not shown). Laminin-332 specific transcripts are barely detectable in LT97 cells cultured in the absence of cytokines but are strongly induced in response to TGF β , as reported previously [16]. TNF α treatment alone also induced the expression of all three genes. The combination of both cytokines led to a very strong synergistic induction particularly of the mRNA of $\alpha 3$ and $\gamma 2$ chains (Figure 1B).

Synergistic effect of TGF β and TNF α on the secretion of heterotrimeric laminin-332 by Smad4-reconstituted human colorectal cancer cells and uncoupled responses of Smad4-deficient cells

We next sought to analyse laminin expression in Smad4-deficient and Smad4-reexpressing SW480 and SW620 human colon cancer cells in response to TNF α and to the combination of TGF β and TNF α cytokines. SW480 cells manipulated to reexpress Smad4 after retroviral transduction have been described previously [19]; unlike SW480 cells expressing very low levels of Smad4 after stable transfection [21], moderate Smad4 overexpression in this cellular model is adequate to restore TGF β responsiveness. Likewise, Smad4-reexpressing SW620 cell clones displayed similar restoration of TGF β responsiveness in transient transfection assays with the currently used p3TPlux and p6SBE promoter-reporter constructs (Additional file 1).

The secretion of laminin-332 could barely be detected in uninduced SW480 and SW620 cells and in cells induced with both cytokines separately (Figure 2A and 2B). In contrast, when cells were coinduced with both cytokines, Smad4-positive SW480 and SW620 cells but not their Smad4-negative counterparts showed secretion of significant levels of laminin-332 (Figure 2A and 2B) indicating that this response is Smad4-dependent.

We next performed expression analyses at the mRNA level in both cell lines at two different time points (at 4 and 24 h) of induction with cytokines (Figure 2C and Additional file 2). As reported previously [16,19], reexpression of Smad4 induced slight increases of basal expression levels of all three laminin-332 chains and restored their TGF β -responsiveness (Figure 2C and Additional file 2). In contrast, TNF α induced expression of the LAMB3 and LAMC2 genes in Smad4-negative cells to a similar or even to a larger extent as compared to Smad4-positive cells. Compared to TNF α responses alone, coinduction with both cytokines did not significantly alter responses in Smad4-negative cells. In

Figure 1 Synergistic induction of laminin-332 in human adenoma cells in response to inflammatory cytokines TGF β and TNF α . (A) Western blot analysis of heterotrimeric laminin-332 expressed by LT97 colorectal adenoma cells. Proteins (8 μ g/lane) prepared from serum-free conditioned media from LT97 cells treated with recombinant TGF β and TNF α for 48 h as indicated were separated on 3-8% tris-acetate gradient gels (Invitrogen) under non-reducing conditions. The blot was probed with a laminin- $\gamma 2$ -specific antibody (polyclonal antibody 2140, PS-A) and reprobed with a transferrin-specific antibody used as a loading control. The bars indicate the relative signal strength normalized for transferrin. Note that the Odyssey detection system (LI-COR) allows for a direct digital quantification of signals. Similar results were obtained in > three experiments. The same signals, although with less sensitivity, were obtained using a commercial antibody (MAB-19562, Chemicon). (B) Northern blot analyses of the LAMA3, LAMB3 and LAMC2 genes prepared with RNAs from LT97 cells treated with cytokines for 24 h. Quantification of mRNA levels was done by phosphorimage analysis and signal strengths normalized with GAPDH. Similar results were obtained in three experiments.

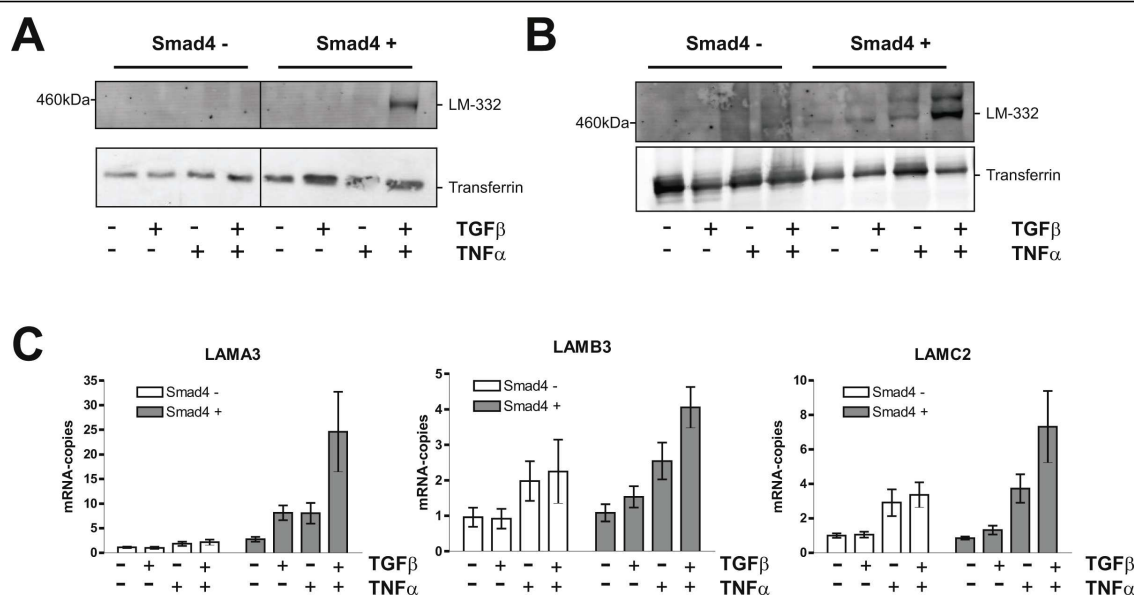

Figure 2 Synergistic effect of TGFβ and TNFα on the secretion of heterotrimeric laminin-332 by Smad4-reconstituted human colorectal cancer cells and uncoupled responses of Smad4-deficient cells. (A and B) Western blot analysis of proteins from conditioned media (12 μg of protein per lane) produced by SW480 (A) and SW620 (B) cells as described in figure 1. (C) Northern blot analysis with RNAs from SW620 cells treated with cytokines for 4 h. Shown in each bar is the mean \pm standard error (n = 3). The additional file 2 provides additional data for SW620 cells treated with cytokines for 24 hours and data for SW480 cells treated with cytokines for 4 and 24 hours.

Smad4-positive cells expression of LAMB3 and LAMC2 was induced in an additive or synergistic manner by both cytokines. Of note, responses of the LAMA3 gene significantly differed from responses of the LAMB3 and LAMC2 genes: Smad4-negative cells display no or negligible induction of LAMA3 expression in response to TNFα alone and to the combination of TNFα and TGFβ in both cell lines and at both time points analysed. In contrast, Smad4-positive SW620 (but not SW480 cells) displayed responsiveness to TNFα alone (Figure 2C and Additional file 2); both, Smad4-positive SW480 and SW620 cells, showed additive or synergistic responses to the combination of both cytokines (Figure 2C and Additional file 2). This expression pattern was consistent with the strongly increased amounts of secreted laminin-332 heterotrimer by Smad4-reexpressing cells in response to combined treatment with TGFβ and TNFα. In addition, these results suggested that loss of Smad4 was responsible for uncoupled regulation of the three laminin genes in response to TNFα.

TNFα induced secretion of monomeric laminin-γ2 by Smad4-deficient colorectal cancer cells

Assembly of the heterotrimeric protein is believed to be a prerequisite for secretion of laminin. Having shown uncoupled induction of γ2 we searched for an intracellular accumulation of the protein by Western blotting but we could not discern specific bands in cell lysates. An analysis of the laminin-332 heterotrimer in conditioned

media by Western blotting with a γ2-specific antibody under non-reducing conditions had previously shown additional diffuse signals at smaller protein sizes in lanes loaded with conditioned media proteins from TNFα treated Smad4-negative cells. A systematic analysis with gel conditions adapted revealed distinct bands corresponding to a protein size of roughly 240 and 140 kilodalton (kDa) with a commercial γ2-specific monoclonal antibody (MAB 19562, Chemicon) (data not shown). An independent γ2-specific antiserum (polyclonal, 2140) delivered an identical pattern (Figure 3A). This result was confirmed with a set of each, three independent Smad4-deficient and Smad4-reexpressing SW620 cell clones (Figure 3B). Thus, Smad4-deficient SW620 cells in response to TNFα apparently release the laminin-γ2 chain in a monomeric form and in a complex with another unknown protein. Under reducing conditions, Smad4-deficient cells showed the unprocessed form of the γ2 chain at 140 kDa, only. Laminin-γ2 chains derived from the Smad4-positive cells came as a mixture of the unprocessed form and a processed form at a size of roughly 105 kDa suggesting that processing may occur in the heterotrimeric configuration (Figure 3C).

Mass spectrometry based confirmation of secreted laminin-γ2

To unequivocally confirm the specificity of the Western blot signals we performed proteomic analysis of conditioned media of Smad4-negative SW620 cells treated

with TNFα by nanoscale liquid chromatography tandem mass spectrometry (nano-LC/MS/MS). Slices were cut form a non-reducing preparative gel corresponding to the 140 kDa signal (band 1) and to the 240 kDa region (band 2). Two slices corresponding to the putative heterotrimer signals (bands 3 and 4) were included as positive controls (Figure 4A). The laminin-γ2-specific peptides identified in gel band 1 are indicated in the amino acid sequence in figure 4B. All results of mass spectrometry and database searches are shown in additional file 3 and summarized in table 1. Among 52 proteins identified in total in gel band 1 the laminin-γ2 chain had the highest Mascot score and highest number of spectral counts which is an indirect measure for its relative abundance [22]. Likewise, laminin-γ2 ranked at position 3 according to the Mascot score among proteins identified in band 2 which corresponds to the Western blot signal at 240 kDa. Also, all three laminin chains were among the most abundant proteins in band 4 according to both their Mascot scores and spectral counts, the presumptive heterotrimer. Band number 3 which corresponds to the second slightly smaller signal

and was regarded as a processed laminin-332 heterotrimer provided surprising results: Whereas the γ2 chain ranked at position 5 with 26 spectral counts, the α3 and β3 chains come at ranks 42 (spectral count 3) and 50 (spectral count 2), only, indicating that their relative amounts are much lower as compared to laminin-γ2. This, in turn, suggests that the Western blot signal at approximately 400 kDa like the signal at 240 kDa corresponds to a protein complex of laminin-γ2 with (an) as yet unknown protein(s).

Induced release of monomeric laminin-γ2 upon transient laminin-α3 knockdown in SW620 cells and its impact on cell migration

Next, we wished to get some insight into the functional consequences of laminin-γ2 release. Accumulation of laminin-γ2 marks the invasive margin of tumors, suggesting that laminin-γ2 is associated with migratory activity. As reexpression of Smad4 induces comprehensive alterations of expression profiles and profoundly affects cellular behaviour through diverse mechanisms, the comparison of Smad4-deficient and Smad4-reexpressing

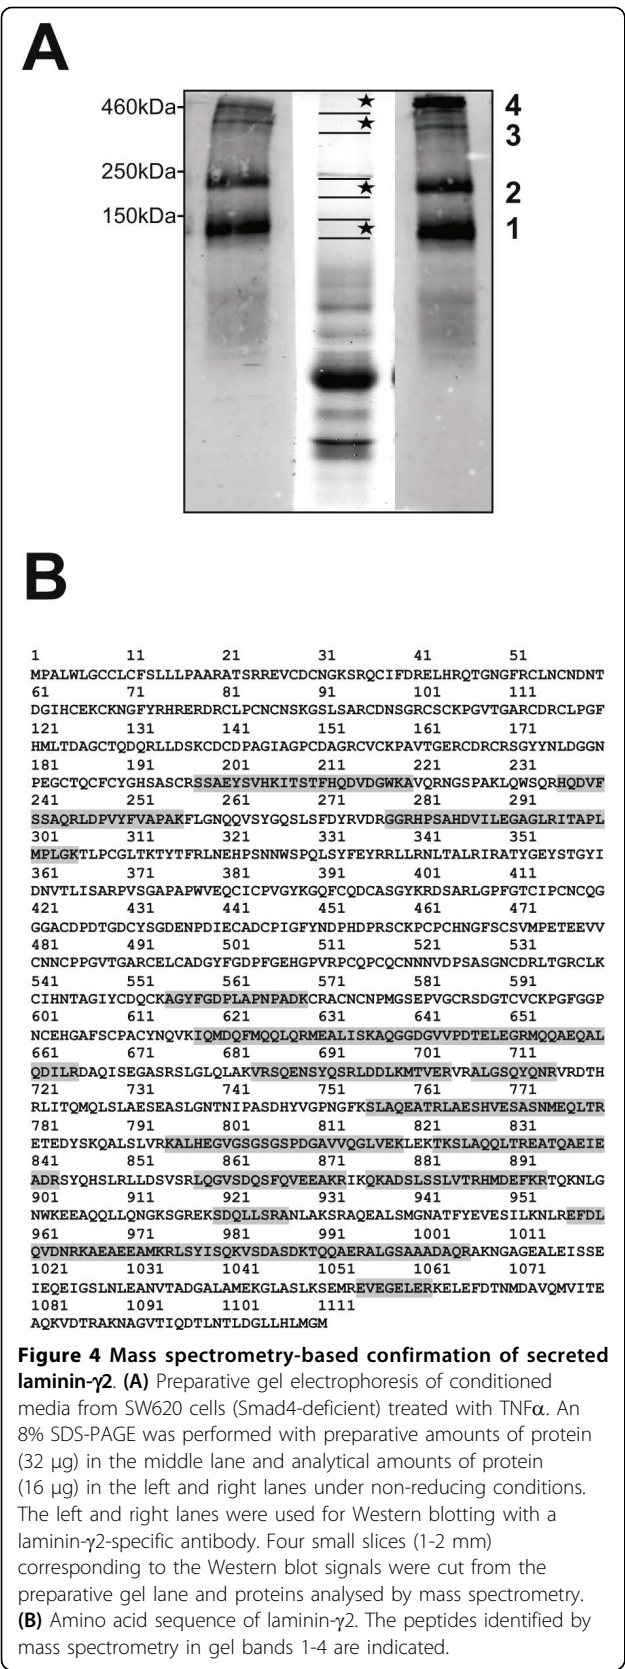

Table 1 Mass spectrometry of proteins and protein complexes reactive with laminin-γ2 specific antibodies as indicated in Figure 4a

	band 1 140 kDa	band 2 240 kDa	band 3 400 kDa	band 4 > 460 kDa
Laminin-γ2	1* (42) [1349.7]	3* (22) [637]	5* (26) [734]	3* (40) [1305.3]
Laminin-β3	-	-	51* (2) [85.1]	4* (40) [1263.9]
Laminin-α3	38* (3) [67.1]	-	43* (3) [117]	2* (48) [1320.8]

*Rank, (spectral counts), [Mascot Score]; Rank according to spectral counts as a quantitative measure for the relative abundance of proteins

cell clones is not adequate to specifically address a putative impact of monomeric laminin-γ2 on cellular migration. Therefore, we set up transient knockdown of LAMA3 expression in order to specifically induce laminin-γ2 monomer secretion in response to TNFα. In fact, transient knockdown of LAMA3 proved functional as assessed by Northern blot analysis (Figure 5A). Suppression of LAMA3 expression resulted in a twofold increase in the 240 and 140 kDa laminin-γ2 signals in conditioned media from TNFα-incubated Smad4-negative SW620 cells (and at very low levels in media from Smad4-positive cells) (Figure 5B). The heterotrimeric laminin-332 in Smad4-positive SW620 cells treated with TNFα was reduced upon transient LAMA3 knockdown as expected (Figure 5B). We then performed transwell migration assays. Both, Smad4-deficient and Smad4-positive cells displayed approximately doubled migration efficiencies upon induced release of laminin-γ2 (and reduced release of heterotrimeric laminin-332) through LAMA3 knockdown (Figure 5C).

Smad4-dependent response of LAMA3 to TNFα is partially mediated via an NF-κB site

We have shown previously, that the molecular mechanisms underlying Smad4-mediated TGFβ responses significantly differ between the three promoters; specifically, the LAMA3 promoter, only, harbours a functional SBE. Here we first asked if this peculiarity of the LAMA3 promoter may also somehow be involved in Smad4-dependent responses to TNFα.

A luciferase construct harbouring the 2 kb region upstream promoter region from the transcription start site reflected TNFα responses of the endogenous LAMA3 gene (Figure 6). Responses to a corresponding construct with the SBE site at position -1.5 kb mutated were indistinguishable (data not shown). *In silico* analysis revealed that this promoter region harbors two

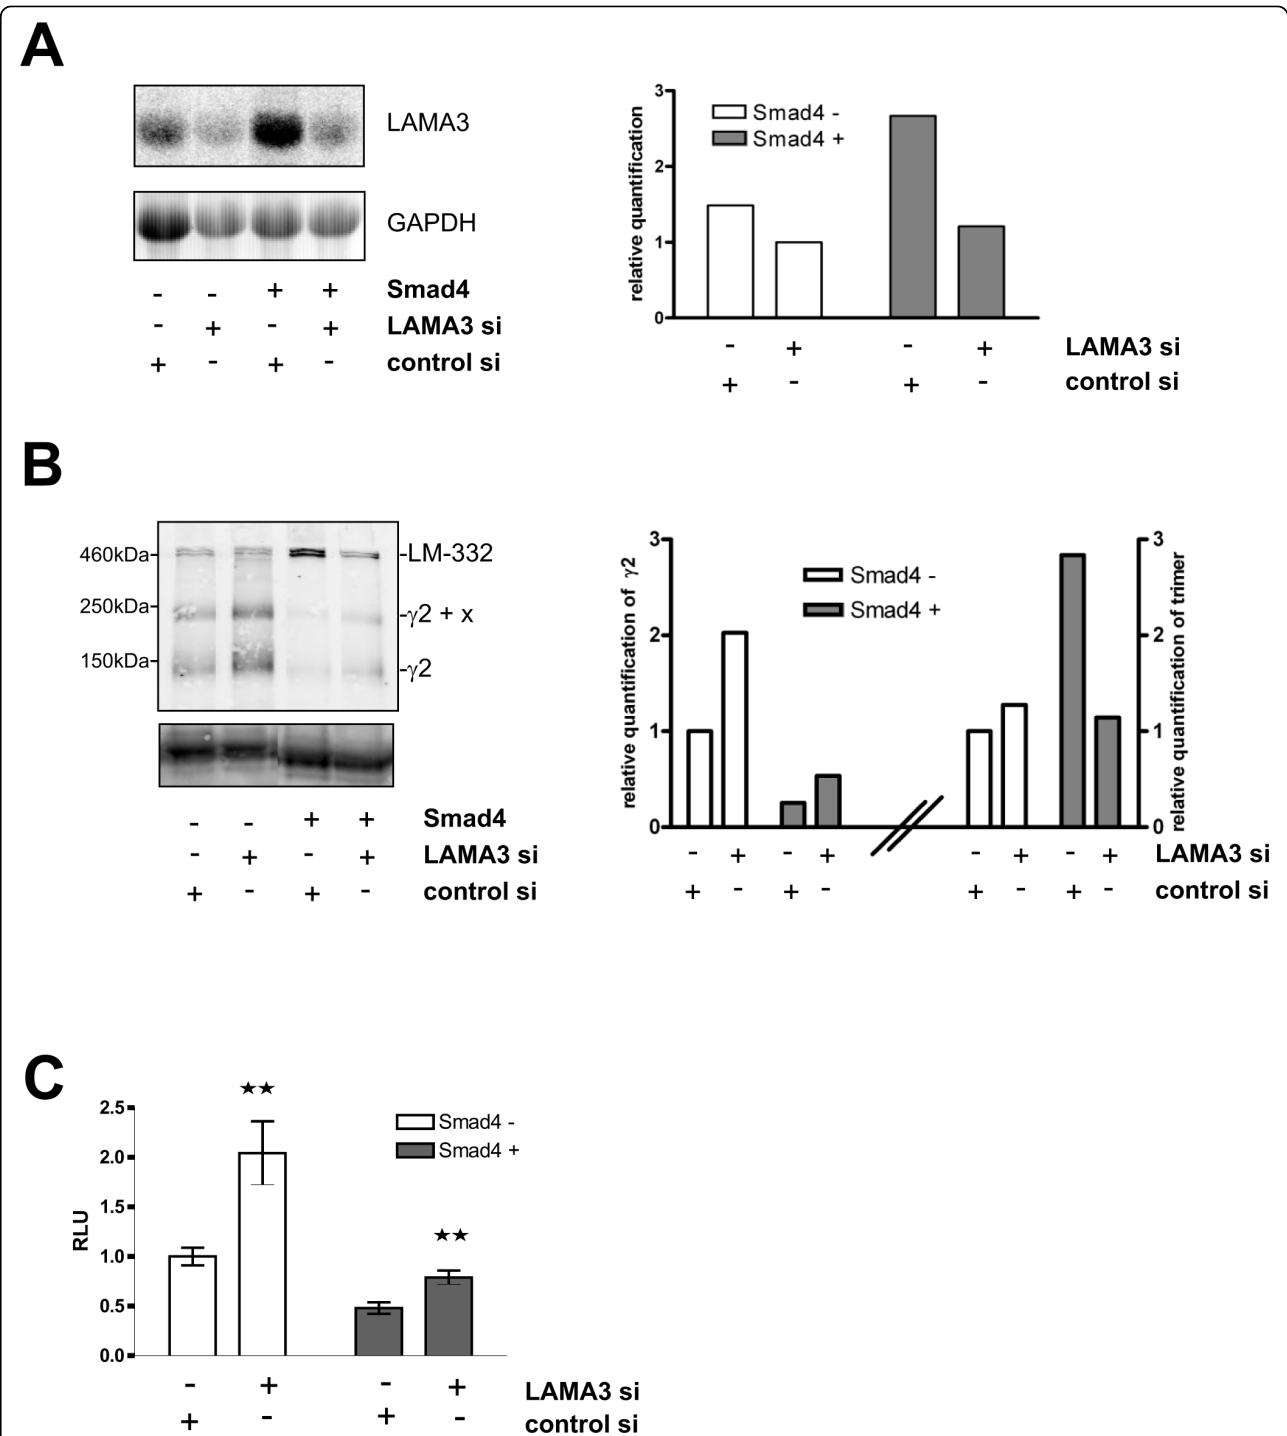

Figure 5 Induced release of monomeric laminin-γ2 upon transient laminin-α3 knockdown in SW620 cells and its impact on cell migration. (A) Northern blot analysis of LAMA3 knockdown in SW620 cells. RNAs were prepared from SW620 cells transiently transfected with LAMA3 siRNA and incubated with TNFα for 24 h. Quantification of LAMA3 messages normalized for GAPDH is indicated. (B) Western blot analysis of laminin-γ2 expression upon transient knockdown of LAMA3. SW620 cells transiently transfected with LAMA3 siRNA or non-targeting siRNA were shifted to serum-free cultures 48 h after transfection and were incubated with TNFα for another 48 h. Proteins from conditioned media (16 μg/lane) were probed with a laminin-γ2-specific antibody (2140). Quantification of the monomer and of the heterotrimer normalized for transferrin is indicated. (C) Migration of SW620 cells as analyzed in a transwell migration assay. SW620 cells transfected with LAMA3 siRNA or non-targeting siRNA were plated in a transwell chamber 24 h after transfection. TNFα was added one day later. Migrating cells were quantified after three days using Cell Titer Glo assay (Promega). Bars show the mean value of four experiments with the standard error of the mean. Statistical analysis was carried out by t test (one-tailed, GraphPad Prism 4.00).

NF- κ B sites located at positions -1.75 and -1.80 kb. Mutation of the upstream NF- κ B site strongly reduced TNF α -inducibility of LAMA3 in Smad4-positive cells but did not affect LAMA3 responses in Smad4-negative cells. Mutation of the downstream site was without effect. AP1 sites have previously been shown to be involved in basal and TGF β -induced LAMA3 expression [19]. Mutation of the most upstream AP1 site at position -272 also led to reduced TNF α inducibility of LAMA3 expression in Smad4-positive cells and

completely abolished the low-level TNF α inducibility of LAMA3 expression in Smad4-negative cells. In summary, we here have implicated an NF- κ B site and to a lesser extent an AP1 site in Smad4-dependent TNF α induction of LAMA3 expression.

In contrast, mutation of a (cryptic) NF- κ B binding site at position -166, the only NF- κ B binding site within the 0.8 kb promoter fragment of LAMC2, did not reduce TNF α inducibility (data not shown). AP1 sites previously implicated in TGF β induction of LAMB3 and

LAMC2 are also involved in TNF α induction of these genes in Smad4-positive and in Smad4-negative cells (Additional file 4).

Discussion

Invading tumor cells are maximally exposed to growth factors and cytokines expressed by stromal cell types. Among these, macrophages have previously been shown to induce angiogenesis [23] and to enhance invasion through the secretion of TNF α [24]. TNF α in cooperation with TGF β dramatically enhanced EMT [24]. On the other hand normal intestinal epithelial cells respond to TNF α and TGF β with an increase in the expression of heterotrimeric laminin-332 [25]. We therefore focused on the analysis of laminin-332 expression in response to cytokines TGF β and TNF α in cell models adequate to reflect the molecular progression of colorectal cancer in vitro. To this end we used pairs of cell clones derived from the human Smad4-deficient colorectal cancer cell lines SW480 and SW620, in which Smad4 expression was stably restored. Responses of Smad4-reexpressing cancer cells were compared to responses of LT97 cells, a cell line derived from a late adenoma and carrying inactivated APC as well as an activated Ki-ras oncogene [20]. LT97 cells secreted increased amounts of heterotrimeric laminin-332 in response to TGF β and TNF α , respectively, and showed extensive synergistic induction of laminin-332 in response to the combination of both cytokines. Smad4-reexpressing colon cancer cells displayed similar, although less pronounced effects. These results are consistent with observations in vivo, that colorectal adenoma cells in the vicinity of infiltrating inflammatory cells display thickening of the basement membrane with streak-like deposits of laminin-332 [10]. Likewise, intestinal epithelial cells in patients afflicted with Morbus Crohn show increased levels of TNF α and induced expression of the constituents of laminin-332 [26,27]. The response of (normal and) premalignant cells to increase expression of laminin-332 may thus be interpreted as a defense mechanism against an inflammatory attack by strengthening the basement membrane barrier.

Synergistic induction of laminin-332 in response to TGF β and TNF α was Smad4-dependent as it did not occur in Smad4-deficient SW480 and SW620 cells. Smad4-deficient cells can induce the expression of the (β 3 and) γ 2 chain of laminin-332 in response to TNF α whereas TNF α induction of the α 3 chain is Smad4-dependent. These results indicate that loss of Smad4 may represent a genetic alteration in the carcinogenic process that can lead to uncoupled regulation of the three genes encoding laminin-332 in response to inflammatory cytokines. We have shown previously that the molecular mechanisms of Smad4-dependent regulation of the three promoters encoding laminin-332 are surprisingly complex. Concerning basal and TGF β -induced expression

levels Smad4 is essential for positive regulation of all three genes. The molecular mechanisms underlying this regulation, however, are significantly divergent between the LAMA3 promoter as compared to the LAMB3 and LAMC2 promoters [19]. Here we show that Smad4 is essential for TNF α induction of LAMA3 but not of LAMB3 and LAMC2 and that AP1 and NF- κ B sites are involved in TNF α -mediated Smad4-dependent LAMA3 induction. Unraveling transcription factor complexes built in response to cytokines and active at the three promoters will require further detailed analyses.

We here focus on functional consequences of uncoupled regulation of the three laminin-332 chains in response to TNF α . The prevailing view suggests that the β 3 and γ 2 chains first form a heterodimer intracellularly, which then binds to α 3 followed by rapid secretion of the heterotrimer [28]. Uncoupled induction at the mRNA level in response to TNF α therefore let us expect an intracellular accumulation of the γ 2 chain in Smad4-deficient cells. Despite repeated attempts, however, intracellular γ 2 could not be detected by Western blotting of cell homogenates. Rather, Smad4-deficient cells release the γ 2 chain in a monomeric form and in two complexes with as yet unidentified proteins as shown by Western blotting and unequivocally confirmed by mass spectrometry.

What are the functional implications of the release of monomeric γ 2? We have shown here, that increased amounts of γ 2 are associated with increased migration and assume that secreted γ 2 may somehow promote tumor invasion. The release of γ 2 may impinge on the composition of the extracellular matrix, alter its functional characteristics and so indirectly affect cell adhesion and migration. Interaction of γ 2 with various ECM molecules including collagen, perlecan and fibulin has been reported [29,30]. Alternatively, monomeric γ 2 may directly affect the tumor cells by interacting with cellular receptors followed by effects on cell signaling which subsequently may result in cell migration. The predominant laminin-receptors are the integrins. Whereas interaction of laminin-332 with cells is predominantly mediated via integrins α 3 β 1 or α 6 β 4 through binding to the laminin-like globular domains of the α 3 laminin chain, the γ 2 chain can bind to α 2 β 1 integrin [30]. Interestingly, it is known that domain III of the γ 2 chain can also directly interact with the EGF-receptor [31]. EGF signaling is a major stimulus for cell migration.

Clues to the functional relevance of γ 2 secreted from cells may come from further analysis of γ 2 complexes in conditioned media. Western blotting as well as results from mass spectrometry indicated that similar amounts of γ 2 are present under non-reducing conditions at 140 kDa corresponding to the monomeric form and at

240 kDa corresponding to a $\gamma 2$ protein complex; thus, we assume that the laminin- $\gamma 2$ chain may interact with another protein of approximately 100 kDa in size. The proteomic analysis surprisingly provided evidence for another as yet unknown $\gamma 2$ complex of about 400 kDa in size. As soon as alternative $\gamma 2$ binding partners will be identified their functional relevance for tumor cell migration and invasion can be addressed.

In summary, our results provide evidence for a sequence of events, in which loss of the Smad4 leads to induction of the laminin $\gamma 2$ chain in response to TNF α followed by the release of monomeric laminin $\gamma 2$ which exerts a proinvasive effect. In conclusion, we here suggest a novel mechanism that may underlie the switch to invasive tumor growth upon loss of the tumor suppressor Smad4.

A large variety of growth factors and cytokines can be expressed at the invasive margin of carcinomas; some of them have previously been suspected to underlie relative overexpression of $\gamma 2$. For example, Olsen et al. investigated the involvement of HGF and found synergistic induction of $\gamma 2$ but not $\alpha 3$ by HGF and TGF β [32]. LAMC2 is an established β -catenin target gene and nuclear β -catenin has been reported to correlate with intracellular accumulation of $\gamma 2$ at invasive margins and in budding tumor cells [15]. Thus, upstream ligands of the wnt gene family induced upon cancer progression may also represent putative inducers of overexpressed $\gamma 2$. Interestingly, the expression of wnts 2 and 5 has specifically been found in macrophages associated with colon tumors [33]. Activated macrophages can indirectly promote Wnt signaling through TNF α [34,35]. We here present data showing that tumor cell responses to TNF α and to the combination of TNF α and TGF β critically depend on Smad4. As extensive crosstalk mechanisms exist between Wnt/ β -catenin and TGF β /Smad pathways [36-38] the detailed understanding of laminin regulation will require future investigations based on an integrated view of signaling networks in normal and oncogenically programmed cells and their respective responses to a dynamic cytokine milieu.

Conclusions

The laminin- $\gamma 2$ chain, which is physiologically deposited in basement membranes as a component of the heterotrimeric laminin-332, is an impressive marker of invasive margins of aggressive carcinomas. In the present study we show that loss of the tumor suppressor Smad4 may be one of the molecular mechanisms that can lead to this relative overexpression of the laminin- $\gamma 2$ chain in response to the inflammatory cytokine TNF α . Moreover, we show that this uncoupled expression leads to the release of laminin- $\gamma 2$ which in turn promotes tumor cell migration. We have thus unraveled a novel molecular

mechanism of how loss of the tumor suppressor Smad4 may promote the carcinogenic process in vivo, where tumor cells interact with stromal cell types and respond to inflammatory cytokines like TNF α expressed by macrophages at the tumor host interface.

Methods

Cell culture and conditioned media

The human colorectal carcinoma cell lines SW480 and SW620 were obtained from the American Type Culture Collection, the human colon adenoma cell line LT97-2 was kindly provided by M Marian (Vienna, Austria). LT97 cells were maintained in Ham's F12 medium with supplements as described [20]. All other cells were maintained in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% fetal calf serum, 2 mM glutamine, 100 U/mL penicillin and 100 μ g/mL streptomycin. When indicated, cells were incubated with 5 ng/mL of TGF β_1 (R&D systems, Minneapolis, MN, USA) and 30 ng/mL of TNF α (Pan Biotech, Aidenbach, Germany) in serum reduced medium (0.5% FCS). Preparation of proteins from serum-free conditioned media was performed as described previously [39].

Production of polyclonal antibody 2140

GST-tagged recombinant laminin- $\gamma 2$ was produced by expressing pGEX $\gamma 2$ lam5 (kindly provided by Dr. M. Failla, IDI-IRCCS, Roma, Italy) in *E. coli*. Affinity-purified laminin $\gamma 2$ -GST protein was confirmed by mass spectrometry (LSMDO, CNRS-EPCM, UMR7509, Strasbourg, France) and injected into rabbits. Antibodies were verified by immunoblotting on HT29-MTX cells and by immunofluorescence on human intestines (not shown) giving identical but stronger signals than MAB19562 (Chemicon, Hampshire, UK).

Western blotting and RNA analyses

For laminin Western blots, samples were subjected to SDS-PAGE on either 8% polyacrylamide gels or on NuPAGE Novex 3-8% Tris-Acetate gels (Invitrogen, Karlsruhe, Germany) and run under conditions either with (reducing conditions to analyze single chain expression) or without dithiothreitol (non-reducing conditions). Heterotrimeric laminin-332, dimeric and monomeric laminin- $\gamma 2$ under non-reducing conditions were detected with monoclonal antibody MAB19562 (Chemicon) and polyclonal antibody 2140. The blots were incubated with a secondary antibody directly coupled with a fluorescent dye (Alexa Fluor 680; Alexa Fluor 800; Invitrogen and Rockland). Signals were detected using the Odyssey Infrared Imaging System (LI-COR Biosciences, Bad Homburg, Germany) which allows for a digital quantification of signals over

a wide linear range of signal intensities. RNA analyses were performed according to standard procedures by Northern blot hybridization and by qRT-PCR as described previously [16,19,21].

Mass spectrometry and mass spectrometric data analysis

Mass spectrometry and mass spectrometric analysis are described in detail in the additional information. In brief, tryptic digest were analyzed by nano-HPLC/ESI-MS/MS using the UltiMate™ 3000 HPLC system (Dionex LC Packings, Idstein, Germany) online coupled to an LTQ Orbitrap XL instrument (Thermo Fisher Scientific, Bremen, Germany). Reversed-phase (RP) capillary HPLC separations were performed as described previously [40].

Peak lists of MS/MS spectra were imported into ProteinScape (version 1.3, Bruker Daltonics, Bremen, Germany) and subsequently correlated with the human International Protein Index database (human IPI v3.41, <http://www.ebi.ac.uk>) containing 72155 protein entries using MASCOT (release version 2.2) [41]. To enable the estimation of a false discovery rate (FDR), the database was concatenated with a duplicate of itself in which the amino acid sequence of each protein entry was randomly shuffled [42]. Protein hits up to an accumulated FDR of 5% were considered as true positive identifications.

Migration assay and transient LAMA3 knockdown

Cells in 500 µL media were added to the upper compartment of 12 well plates supplemented with inserts (8 µm pore size; BD Falcon). Cytokines were added one day later and cells incubated for another 72 hours at 37°C. Cells which had passed the pore membrane were quantified using Cell Titer Glo (Promega, Madison, WI, USA) in accordance with the manufacturer's recommendations.

For siRNA experiments cells were grown to a confluency of 50% and transfected with ON-TARGETplus siRNA (LAMA3, J-011071-05, Dharmacon, Lafayette, CO, USA) or Dharmacon ON-TARGETplus Nontargeting siRNA as a control, respectively, using Dharmafect (Dharmacon). For migration assays cells were plated into transwells 24 h after transfection.

Promoter analyses

Promoter construction and transient transfections were performed as previously described [16,19] with minor modifications. Cells were grown to a confluency of approximately 50-70% in 96-well plates, medium was changed to serum reduced medium (0.5% FCS) and cells were transfected using Effectene (Qiagen, Hilden, Germany). The next day cytokines were added and cells were harvested 4 h and 24 h after transfection. Luciferase assays were carried out as triplicates and quantified using a luminometer (GloMax™ 96 Microplate, Promega,

Madison, WI, USA) and the Dual-Luciferase-Reporter Assay System (Promega).

Additional file 1: Restoration of TGFβ responsiveness through re-expression of Smad4.

Smad4 expression was stably restored by retroviral transduction in Smad4-deficient human SW620 colon carcinoma cells. **(A)** Western blot analysis for the human Smad4 protein on total protein extracts of each three Smad4-negative and six Smad4-positive clones of SW620 cells (TJ: empty vector control clones, DTJ: Smad4- (DPC4) positive clones). **(B and C)** Transient transfections with p3Tlux (B) and p6SBE (C) reporter vectors of each four Smad4-negative and five Smad4-positive derivatives of SW620 cells. Normalized promoter activity of p3Tlux (a fusion construct of the PAI-1 and collagenase-1 promoters harboring AP1 sites) and p6SBE (a 6fold concatemer of the SBE) as analyzed in transient transfections of TGFβ-treated (24 h) and -untreated Smad4 negative and Smad4 re-expressing cells. Transient transfection experiments were repeated in triplicates. The bars show the mean values with the standard error of the mean. For further experiments we defined a standard clone set consisting of clones TJ3, 9 and 10 and DTJ8, 16 and 21.

Additional file 2: Synergistic effect of TGFβ and TNFα on the expression of LAMA3, LAMB3 and LAMC2 genes by Smad4-reconstituted human colorectal cancer cells and uncoupled responses of Smad4-deficient cells.

(A and B) Semi-quantitative RT-PCR analysis of the LAMA3, LAMB3 and LAMC2 genes prepared with RNAs from SW480 cells treated with recombinant TGFβ and TNFα for 4 h (A) and 24 h (B). Shown in each bar is the mean ± standard error of 10 measurements. **(C)** Northern blot analysis of the LAMA3, LAMB3 and LAMC2 genes prepared with RNAs from SW620 cells treated with recombinant TGFβ and TNFα for 24 h. Signals were quantified by phosphorimage analysis and normalized for GAPDH expression (n = 3).

Additional file 3: Mass spectrometry of proteins and protein complexes reactive with laminin-γ2 specific antibodies as indicated in Figure 4a.

Proteins were identified through SDS-PAGE combined with nano-high performance liquid chromatography coupled online with electrospray ionization tandem mass spectrometry. MS/MS data were used for protein identification by performing searches in the human IPI database with Mascot and for the calculation of spectral counts as a relative quantitative measure for protein abundance. Proteins were identified with a false discovery rate of 5%.

Additional file 4: TNFα induction of LAMB3 and LAMC2 is conferred through AP1 binding sites.

Normalized promoter activities of LAMB3 **(A)** and LAMC2 **(B)** wild-type and mutated promoter constructs. SW480 cells were plated in 96-well plates and transfected with the indicated promoter constructs using the Dual-Luciferase-Reporter Assay System (Promega). Mutagenesis of both AP1 sites in the LAMB3 promoter significantly reduced TNFα responsiveness in Smad4 reexpressing cells. TNFα induction of LAMC2 is conferred through the upstream AP1 site in a Smad4-independent manner. Bars show the mean value of three experiments with the standard error of the mean.

Acknowledgements

We thank B Marian (Vienna) for providing LT97 cells, M Failla (IDI-IRCCS, Roma) for the pGEX γ2lam5 expression vector, M Vanier (U682, Strasbourg) for the production of the laminin γ2 antibodies (#2140), JM Strub (LSMDO, CNRS, Strasbourg) for mass spectrometry analysis of the laminin γ2-GST protein, and S Hoppe and A Schöneck for excellent technical assistance. This work was supported by grants from the Ruhr-University Bochum, FoRUM Program (F510-2006) and from INCa (Canceropôle Grand-Est to PSA).

Authors' contributions

DZ designed the study, carried out Western Blot, RNA and promoter analyses, performed transient knockdown and migration experiments and drafted the manuscript. BW performed mass spectrometry analyses. MBM and HB participated in expression analyses. SK-S, HEM and WS contributed to the design of the study. PS-A established the novel polyclonal laminin- γ 2 antibody 2140 and contributed to the manuscript. IS-W is the PI, designed the study and drafted the manuscript. All authors have read and approved the final manuscript.

Competing interests

The authors declare that they have no competing interests.
