ABSTRACT Membrane structures of the mixtures of ganglioside G_{M1} and endosome specific lipid, bis (monoacylglycerol) phosphate (BMP, also known as lysobisphosphatidic acid) were examined at various pH conditions by freeze-fracture electron microscopy and small-angle x-ray scattering. At pH 8.5–6.5, a G_{M1}/BMP (1:1 mol/mol) mixture formed small vesicular aggregates, whereas the mixture formed closely packed lamellar structures under acidic conditions (pH 5.5, 4.6) with the lamellar repeat distance of 8.06 nm. Since BMP alone exhibits a diffuse lamellar structure at a broad range of pH values and G_{M1} forms a micelle, the results indicate that both G_{M1} and BMP are required to produce closely stacked multilamellar vesicles. These vesicles resemble membranous cytoplasmic bodies in cells derived from patients suffering from G_{M1} gangliosidosis. Similar to G_{M1} gangliosidosis, cholesterol was trapped in BMP vesicles in G_{M1}- and in a low pH-dependent manner. Studies employing different gangliosides and a G_{M1} analog suggest the importance of sugar chains and a sialic acid of G_{M1} in the pH-dependent structural change of G_{M1}/BMP membranes.

A characteristic feature of endosomes along with the degradative endocytic pathway is the accumulation of vesicles within the organelle (1,2). Recently, it has been shown that the unconventional phospholipid bis(monoacylglycerol) phosphate (BMP), also known as lysobisphosphatidic acid, LBPA can induce the formation of multivesicular liposomes that resemble multivesicular endosomes (3). BMP is a structural isomer of phosphatidylglycerol with characteristic *sn*-1, *sn*-1' glycerophosphate stereoconfiguration (4,5). This lipid is highly enriched in the specific internal membrane domains of multivesicular late endosomes where the lipid comprises >70% of the total phospholipids (6,7). It has been reported that late endosomes/lysosomes change their organization from multivesicular to multilamellar membranes under different pathological conditions and by treatment with certain drugs. These multilamellar vesicles, in which membranes are tightly stacked, are called membranous cytoplasmic bodies (MCB). Although the involvement of BMP domains in late endosomes (8) and lipid-protein interaction (9) have been suggested, the mechanism of the formation of MCB is not well understood. Recently we have shown that a drug that induces multilamellar endosomes alters BMP liposomes from swollen and loosely packed lamellar vesicles to closely stacked multilamellar structures at low pH (10).

Sphingolipidosis is a genetic disease defective in the proteins involved in sphingolipid metabolism (11). Accumulation of MCBs is a characteristic feature of this disease.

Different sphingolipids are accumulated depending on the defect. These lipids, such as sphingomyelin and galactosylceramide, themselves form multilamellar structures in aqueous solution. In contrast, in G_{M1} gangliosidosis, micelle-forming lipid G_{M1} is extensively accumulated and still MCBs are formed. Therefore, it is of interest to investigate the conditions in which the accumulation of G_{M1} induces the formation of closely stacked membranes. In our study, we examined the membrane structure of ganglioside/BMP mixture in neutral and acidic pH conditions, the latter of which resembles the lumen of late endosomes/lysosomes.

First, we examined whether the accumulated G_{M1} colocalize with the BMP-rich membrane domains in intact cells. The addition of exogenous ganglioside to cultured cells mimics the behavior of the cells from gangliosidosis (12). Diffuse fluorescence was observed when cultured human skin fibroblasts were fixed, permeabilized, and labeled with fluorescently labeled cholera toxin, which recognizes G_{M1} (see Fig. 4 of the Supplementary Material). In contrast, intracellular compartments were brightly labeled with cholera toxin when cells were grown in the presence of 10 μM G_{M1}. The fluorescence was colocalized with that labeled with anti-BMP antibody. The result suggests the presence of BMP and G_{M1} in the same membrane domains. We next examined the

membrane structure of BMP/ G_{M1} complex. 2,2'-Dioleoyl-*sn*-1,*sn*-1'-BMP is a major molecular species of naturally occurring BMP (7,13). We chemically synthesized 2,2'-dioleoyl-*sn*-1,*sn*-1'-BMP (14) and measured the structure of the membranes in the presence of G_{M1} by using electron microscopy and small-angle x-ray scattering (SAXS). Fig. 1 shows freeze-fracture electron micrographs of the G_{M1} /BMP (1:1 mol/mol) mixture at pH 7.4 and 4.6. The particles observed at pH 7.4 were mainly unilamellar vesicles, as demonstrated in cross-fracture images, whereas the results at pH 4.6 indicated structures filled with multiple layers or large multilamellar vesicles. Each layer was closely stacked, and the distance between the adjacent layers was <10 nm. The size of vesicles at pH 7.4 was ~ 100 – 300 nm diameter in contrast to ~ 300 nm– 3 μ m diameter at pH 4.6. Similar results were observed by negative-staining electron microscopy (data not shown). In Fig. 1, pH dependence of the SAXS patterns of the G_{M1} /BMP (1:1 mol/mol) mixture are also shown. At pH 8.5–6.5, the SAXS profiles displayed similar curves, exhibiting an evident minimum at $q = \sim 0.55$ nm^{-1} and a broad bell-shaped peak at $q = \sim 1$ nm^{-1} . These are characteristics of a scattering curve from an assembly of identical small particles. It is reported that dioleoyl BMP forms a diffuse lamellar structure at a pH range of 3.0–8.5 (10,15), whereas G_{M1} forms a stable micellar structure at a pH range of 3.6–8.0 (16). Considering the negatively charged bulky headgroup of G_{M1} , which gives a high curvature when inserted into the membrane, it is expected that the G_{M1} /BMP mixture formed such compact aggregates. At pH 5.5, however, the SAXS pattern exhibited two small peaks at

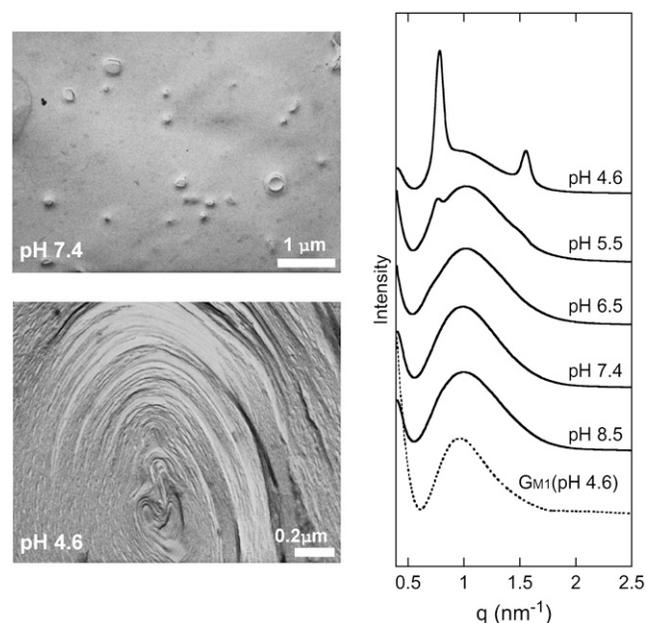

FIGURE 1 (Left) Freeze-fracture electron micrographs of G_{M1} /BMP (1:1 mol/mol) mixture at different pH. (Right) SAXS patterns of G_{M1} at pH 4.6 and G_{M1} /BMP mixture at different pH.

$q = 0.78$ and 1.56 nm^{-1} in addition to the broad peak at $q = \sim 1$ nm^{-1} . These two peaks correspond to the first- and second-order diffraction peaks from a lamellar structure with an 8.06 nm repeat distance. At pH 4.6, the first- and second-order peaks became much more evident, indicating that the acidic pH condition transformed the G_{M1} /BMP mixture from small aggregates to a planar lamellar structure. The dose response of G_{M1} indicates that the alteration of the membrane structure was inducible by the addition of as low as 10% of G_{M1} (see Fig. 5 in the Supplementary Material) at low pH.

One of the consequences of the storage of sphingolipids in MCBs, including G_{M1} , is the accumulation of cholesterol. It is proposed that the preferential association of sphingolipids and cholesterol causes the accumulation of cholesterol in MCBs (8). We investigated whether the G_{M1} /BMP membrane traps cholesterol in a pH-dependent manner (Fig. 2). Methyl- β -cyclodextrin ($M\beta$ CD) extracts cholesterol from the membrane. Extraction of cholesterol from BMP and G_{M1} /BMP membranes by $M\beta$ CD was investigated at pH 7.4 and 4.6. Cholesterol was equally extracted from the BMP liposomes irrespective of pH. The presence of G_{M1} did not affect the extraction at pH 7.4. In contrast, the extraction of cholesterol was significantly reduced in the presence of G_{M1} at pH 4.6. The addition of 10 mol % cholesterol did not alter the gross structure of the G_{M1} /BMP membranes (data not shown). This result suggests that the formation of the closely packed multilamellar structure of G_{M1} /BMP in an acidic environment prevents the cholesterol extraction by $M\beta$ CD.

Fig. 3 shows the examination of the effects of various gangliosides on the membrane structure of BMP at pH 4.6. Similar to G_{M1} /BMP, lamellar diffraction peaks were observed in G_{M2} /BMP membrane. However, the G_{M3} /BMP and G_{D3} /BMP mixtures did not exhibit clear lamellar peaks, suggesting that a branched carbohydrate chain is required for

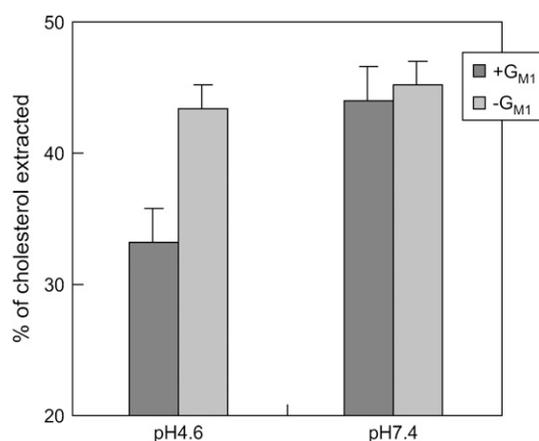

FIGURE 2 Cholesterol extraction from BMP/cholesterol and G_{M1} /BMP/cholesterol (10 mol % cholesterol) membranes at different pH.
