observed in GBs from a control group, represented by 10 alithiasic GBs removed from patients with neoplastic diseases not involving the GB. The number of CD68 positive macrophages in the muscle layer of GBs from gallstone patients was significantly higher compared to that in control patients. In UDCA-treated patients, the number of CD68 positive macrophages, in GB muscle, was significantly lower when compared to that in placebo-treated patients. Positive COX-2 expression was almost exclusively present in macrophages within the muscle layer (fig 1). The number of COX-2 positive cells was higher in muscle from symptomatic gallstone patients compared to controls and, likewise macrophages, significantly lower following UDCA treatment (table 1, fig 1). A direct and significant correlation was observed between positivity for CD68 and COX-2 (Spearman’s r = 0.7, p<0.001). As in our previous study, the production of PGE2 was significantly lower, following UDCA than after placebo. Furthermore, muscle contraction, induced by increasing concentrations of CCK-8 (assessed in four patients in each group) was significantly higher in the UDCA, compared to placebo group (maximal contraction to CCK-8 10⁻¹⁰ mol/l was 25.1 (SD 3) vs 12 (SD 4)%, respectively; p<0.001). Our more recent data show that an inflammatory macrophage infiltrate is present in the GB muscle layer of cholesterol gallstone patients. UDCA decreases the presence of macrophages in the muscle layer and confirms improvement in GB muscle cell contraction. These results suggest that activated macrophages play a role in muscle cell dysfunction and add insight into the anti-inflammatory action of UDCA, which may explain some of the therapeutic effects of this bile acid in liver diseases as well as other gastrointestinal inflammatory conditions.

Pathological lesions in colonic biopsies during Parkinson’s disease

Parkinson’s disease (PD) is a neurodegenerative condition that affects 1% of the population over 65 years of age. The two pathological hallmarks of PD are a loss of dopaminergic neurons in the substantia nigra (SN) and the presence of cytoplasmic eosinophilic inclusions termed Lewy bodies (LBs), whose main component is phosphorylated α-synuclein. This degeneration of SN neurons leads to a dopamine deficiency...
responsible for the major motor symptoms. Nevertheless, it has become increasingly evident that PD is a multicentric neurodegenerative process that also affects neuronal structures outside the SN. In this context, various reports performed on surgical or autopsy specimens have shown that the enteric nervous system (ENS) is affected during PD. However, it is still a matter of debate whether these alterations occur early in the course of the disease. This is mainly due to a lack of accessibility to the ENS in the living patients. Therefore, demonstrating (1) the ability to study the ENS using routine colonic biopsies and (2) the presence of lesions characteristic of PD could be relevant for an early diagnosis of the disease and to better understand its pathophysiology and characteristics of PD could be relevant for an early diagnosis of the disease and to better understand the generative process that also affects neuronal structures outside the SN.

In this context, we performed routine colonic biopsies in five PD patients complaining of functional constipation (63 (SD 7) years, three men; all had disease duration >5 years). Five healthy age-matched patients (61 (SD 6.5) years, one man) requiring a total colono-scopy for colorectal cancer screening were included as controls. They had no known neurological disease. None suffered from functional digestive symptoms. In order to avoid any specific role for chronic constipation, we included three additional non-age-matched patients (52 (SD 5) years, no men) who underwent total colonoscopy for the assessment of a chronic intractable constipation as additional controls. Written consent was obtained according to the principles of the Declaration of Helsinki.

Four biopsies were taken from the ascending colon during colonoscopy. Biopsies were performed using standard biopsy forceps without needles (FB210K; Olympus, Tokyo, Japan). Samples were immediately immersed in 4°C saline solution and microdissected in order to separate the submucosa (containing the internal submucosal plexus) from the mucosa. The submucosa were then fixed in 4% paraformaldehyde. Immunohistochemical studies were then performed on these tissues using a combination of antibodies against rabbit anti-tyrosine hydroxylase (TH) (1:500, Pel-Freez, Rogers, Arkansas, USA), rabbit anti-dopamine-β-hydroxylase (DBH) (1:250, Millipore, Saint-Quentin-en-Yvelines, France), mouse anti-Hu C/D (1:200, Invitrogen, Cergy-Pontoise, France), rabbit anti-phosphorylated α-synuclein (1:5000, WAKO, Osaka, Japan) or rabbit anti-phosphorylated α-synuclein (1:250, Millipore, Saint-Quentin-en-Yvelines, France), mouse anti-Hu C/D (1:200, Invitrogen, Cergy-Pontoise, France), rabbit anti-dopamine-β-hydroxylase (DBH) (1:250, Millipore, Saint-Quentin-en-Yvelines, France), mouse anti-Hu C/D (1:200, Invitrogen, Cergy-Pontoise, France), rabbit anti-phosphorylated α-synuclein, revealed that 4 out of 5 PD patients had phospho-α-synuclein-IR neurites (identified with neurofilament (NF) in the submucosa (fig 2A,F). These phospho-α-synuclein-IR neurites were absent in both control and constipated patients. In some cases, large aggregates were observed in dystrophic NF-IR neurites (fig 2E), a pattern reminiscent of Lewy neurites. Taken together, our pilot study showed that routine colonic biopsies can be used to study the submucosal plexus of the ENS. In addition, we identified for the first time in the gut of living PD patients lesions similar to the ones observed in the brain. This technique could be a reliable tool to detect early lesions in the gut during the course of PD in order to better understand the pathogenesis of the disease and/or to identify novel biomarkers.

4

In control patients, individual biopsies contained 11.2 (SD 7.9) ganglia and each ganglia contained 5.6 (SD 2.2) Hu-immunoreactive neurons. In PD patients, the number of ganglia per biopsy was similar to controls (15.6 (SD 5.5); p = 0.22). In addition, the number of Hu-IR neurons per ganglion in PD was unchanged as compared to controls (7.0 (SD 1.6); p = 0.25) (fig 1A,C). Constipated controls did not differ from PD patients in the number of ganglia per biopsy (11.3 (SD 1.5); p = 0.57) or in the number of neurons per ganglion (5.5 (SD 0.6); p = 0.19) (fig 1C).

In healthy controls, 11.6 (SD 5.0)% of Hu-IR neurons were TH-IR. In PD patients, the proportion of TH-IR neurons was unchanged as compared to controls (12.3 (SD 3.5)%; p = 0.80) (fig 1D-F). In constipated patients, the proportion of TH-IR neurons was similar to the one of PD patients (8. (SD 2.7)%; p = 0.12) (fig 1F). In all groups no neuronal body was DBH positive, suggesting that all TH-IR neurons in the submucosal plexus were dopaminergic. These results are consistent with a previous report by Singaram et al showing the absence of loss of TH-IR neurons in the submucosal and myenteric plexuses of PD patients, suggesting that it is not a marker of choice for detecting PD lesions in the ENS.

However, immunohistochemical staining with an antibody against phosphorylated α-synuclein, revealed that 4 out of 5 PD patients had phospho-α-synuclein-IR neurites (identified with neurofilament (NF) in the submucosa (fig 2A,F). These phospho-α-synuclein-IR neurites were absent in both control and constipated patients. In some cases, large aggregates were observed in dystrophic NF-IR neurites (fig 2E), a pattern reminiscent of Lewy neurites.
Ethics approval: The study protocol was approved by the local Committee on Ethics and Human Research on 27 February 2007.

TC and TL as well as PD and MN contributed equally to this work.

CORRECTION
doi:10.1136/gut.2007.119446corr1

R Spiller, Q Aziz, F Creed, et al. Guidelines on the irritable bowel syndrome: mechanisms and practical management (Gut 2007;56:1770–98). In paragraph 4.4.1 the sentence “This in turn acts on the adrenal medulla, resulting in cortisol secretion into the circulation” should read “This in turn acts on the adrenal cortex, resulting in cortisol secretion into the circulation”.

Figure 2  Phospho-α-synuclein-positive submucosal neurites differentiate Parkinson’s disease patients from controls. Double labelling with antibodies against neurofilament (NF) (A,B) and phosphorylated α-synuclein (C,D) revealed that some NF-immunoreactive (IR) neuritic structures were also phospho-α-synuclein-IR (merged image in E,F) in the majority of Parkinson’s disease patients, but in none of the controls. Occasionally the inclusion-bearing neurites displayed dystrophic alterations (A,C,E). Scale bar: 30 μm.

ANSWER

From the question on page 1673

The patient had a large inflammatory abdominal aortic aneurysm. The abdominal CT scan shows a large infrarenal aortic aneurysm with a maximum diameter of 7.5 cm extending into the iliac vessels. There is an enhancing soft-tissue cuff surrounding the anterolateral margin of the aneurysm. The aneurysm appears to compress the third part of the duodenum (fig 1 below), which, however, was not detected at endoscopy. These CT findings were suggestive of an inflammatory aneurysm. Inflammatory abdominal aortic aneurysms represent 3–10% of all abdominal aortic aneurysms and occur predominantly in men.1 They differ from atherosclerotic aneurysms in that patients often present with abdominal symptoms or anorexia, weight loss, and raised inflammatory markers. CT has a specificity of 99.7% for diagnosis of inflammatory aneurysms,2 usually showing periaortic fibrosis as a cuff of enhancing soft tissue surrounding the anterolateral margin of the aneurysm. If periaortic fibrosis is extensive, adjacent abdominal structures may be compressed and adherent, most commonly the third part of the duodenum.1 Although rare, inflammatory abdominal aortic aneurysms should be kept in mind as a cause of abdominal pain and/or anorexia, weight loss, and raised inflammatory markers. The natural history of inflammatory abdominal aortic aneurysms remains unknown, with 3.3–14% patients presenting with acute or chronic rupture.1 As regards to management, the literature supports an operative approach with a 30 day operative mortality rate of up to 9%.1 Complete regression of fibrosis and inflammatory process occurs in up to one-half of patients at long-term follow-up post-operatively. Clinical symptoms (such as weight loss and gastrointestinal symptoms) reverse in 93% of the patients after an operation.3 Endovascular therapy is also a potential treatment.
