Key words: Vav, T cell, leukemia, murine leukemia virus, retrovirus

Vav1 is expressed exclusively in hematopoietic and is required for T cell development and activation. Vav1-deficient mice show thymic hypopcellularity due to a partial block during thymocyte development at the DN3 stage and between the double positive (DP) and single positive (SP) transition. Vav1 has been shown to play a significant role in several non-hematopoietic tumors but its role in leukemogenesis is unknown. To address this question, we investigated the role of Vav1 in retrovirus-induced T cell leukemogenesis. Infection of Vav1-deficient mice with the Moloney strain of murine leukemia virus (M-MuLV) significantly affected tumor phenotype without modulating tumor incidence or latency. M-MuLV-infected Vav1-deficient mice showed reduced splenomegaly, higher hematocrit levels and hypertrophic thymi. Notably, Vav1-deficient mice with M-MuLV leukemias presented with markedly lower TCRβ/cD3 levels, indicating that transformation occurred at an earlier stage of T cell development than in WT mice. Thus, impaired T cell development modulates the outcome of retrovirus-induced T cell leukemias, demonstrating a link between T cell development and T cell leukemogenesis.
Thus, integrated proviruses can affect many genes and induce leukemia in a multistep/multigene fashion, rather than through a unique mutation in a specific gene. Because of the important role of Vav1 in tumorigenesis and T cell development, we infected newborn mice with the Moloney strain of MLV (M-MuLV), which commonly induces leukemia/lymphoma of T cell origin. In neonatal mice, M-MuLV-induced leukemogenesis is particularly efficient, in part due to the absence of an antiviral immune response through tolerance-inducing mechanisms. As the potential role of an antiviral immune response is limited in this model, we used neonatal WT and Vav1-/- mice to assess the role of Vav1 in the development of retrovirus-induced leukemias. While the absence of Vav1 did not affect disease incidence or latency, the phenotype of leukemic cells in the thymus and periphery were distinct.

**Results**

Development of leukemias in WT and Vav1+ mice following M-MuLV inoculation. To investigate the role of Vav1 in T cell development, we infected newborn Vav1+/+, Vav1-/- and Vav1+ mice intraperitoneally with M-MuLV, a retrovirus known to induce the development of T lymphomas. There was no significant difference in M-MuLV-induced disease incidence or latency with approximately 50% of mice developing clinical signs of disease by day 115 post-infection (Fig. 1). By day 200 post-infection, all mice had developed leukemia.

M-MuLV-induced leukemia is characterized by increases in spleen size and, to a lesser extent, the thymus. Despite similar survival rates, Vav1+ mice presented with clinical characteristics that distinguished them from Vav1+ and Vav1+ mice (Fig. 2). The hematocrits of healthy mice of all genotypes ranged between 45 to 50% (data not shown). M-MuLV-inoculated Vav1+ and Vav1-/- mice presented with significantly lower hematocrits, ranging from 40 to 42% (Fig. 2A). Notably, the hematocrits in M-MuLV-inoculated Vav1+ mice with leukemias were significantly higher (mean of 47%, p < 0.001), suggesting that erythropoiesis was less affected in these mice than in their WT counterpart or that they showed a lower percentage of leukemic T cells in the periphery.

Splenic cellularity in healthy mice of all genotypes was equivalent with a weight of approximately 0.08 g (Fig. 2B). Upon M-MuLV-induced leukemogenesis, Vav1+ and Vav1-/- mice developed severe splenomegaly (10-fold weight increase) that correlated with increased cellularity (Fig. 2B and C). While splenomegaly was also detected in M-MuLV-infected Vav1+ mice, their spleens were significantly smaller and showed decreased cellularity as compared with leukemic Vav1+ and Vav1-/- mice (Fig. 2B and C).

Under conditions of M-MuLV-induced leukemia, Vav1+ and Vav1+ mice showed small increases in thymic size (Fig. 2D). However, in Vav1+ mice, which under normal conditions have reduced thymic cellularity due to a lower number of DP cells, M-MuLV-induced leukemia resulted in a massive increase in the size of the thymus (Fig. 2B and D). The thymi of Vav1+ infected mice often invaded the entire thoracic cavity and indeed, these mice often suffered from respiratory problems during the latter stages of disease.

Distinct thymocyte profiles in Vav1+ and Vav1+ mice with M-MuLV-induced leukemia. M-MuLV-induced T cell leukemogenesis is often associated with the expansion and accumulation of thymocytes with an immature phenotype. To study the phenotype of thymocytes accumulating in the different mice cohorts, we first assessed the CD4/CD8 profiles. While profiles of thymocytes from infected mice showed some variability, they differed significantly from those of healthy mice. CD4/CD8 staining from individual mice is presented in Figure 3A. The majority of lymphomagenic thymi from leukemic Vav1+ mice harbored a high percentage of CD4-expressing cells, as also reported following infection with the radiation leukemia virus (RadLV). In healthy Vav1+ mice, the percentages of DN and SP thymocytes were modulated, with significantly higher levels of the former (p < 0.05) and lower levels of the latter (p < 0.05; Fig. 3A and B) and reviewed in ref. 11). Leukemia development in Vav1+ mice was associated with higher variability; approximately half the mice harbored >40% single positive CD4 cells (SP4) while the remainder harbored <20% SP4 cells (Fig. 3A and B). To study the differentiation state of these SP4 cells, we monitored TCRβ expression. In agreement with previously published data in reference 27, thymi of healthy Vav1+ mice had a significantly lower level of TCRβ-hi cells (Fig. 3C and Table 1), indicative of an immature stage of thymopoiesis as compared with WT mice where the majority of cells were mature TCRβ-hi SP4 thymocytes (49% and 73%, respectively). While TCRβ expression remained elevated on SP4 thymocytes in leukemic Vav1+ mice, it was undetectable on the vast majority of SP4 thymocytes from Vav1+ lymphomagenic thymi. Altogether, our results indicate that lymphomagenic thymocytes from Vav1+ mice have a more immature phenotype than those present in the WT counterpart.
given that M-MuLV infection targets proliferating cells, it was of interest to assess the cell cycle entry of different thymocyte populations. The percentage of DP thymocytes slightly decreased in WT mice between 3 d of age (the time point of M-MuLV inoculation) and 2 mo of age (Fig. 5A) whereas it was not statistically different in Vav1–/– mice. While the presence of SP4 and SP8 thymocytes augmented with age, they remained significantly lower in Vav1–/– than WT mice.

The entry of thymocytes into cell cycle, was monitored as a function of Ki67 expression, a protein upregulated during mid G1 phase. The percentage of Ki67+ cells within the DP thymocyte subset was not modulated by either age or the presence of Vav1 (Fig. 5A). The percentages of Ki67+ DN cells decreased with age but this phenomenon was observed in both WT and Vav1–/– mice. Notably, within the SP8 population, the relative proportion of Ki67+ cells was higher during the newborn period, with greater than 50% of this subset expressing Ki67 in neonatal Vav1–/– mice. However, the total numbers of Ki67+ SP8 thymocytes were still lower in Vav1–/– mice due to the relative paucity of this population. Almost identical data were obtained in the SP4 population. Importantly, the increased

Furthermore, there was a significant increase in DN thymocytes in lymphomagenic thymi from both WT and Vav1+ mice (Fig. 3). As Vav1+ mice have a partial block between DN3 and DN4 thymocyte stages (Fig. 4 and reviewed in ref. 11), it was of interest to determine whether leukemogenesis would result in the accumulation of distinct DN populations in WT and Vav1+ mice. The majority of DN cells in leukemic WT mice had a CD44+CD25– (DN1) phenotype, while the DN profile in leukemic Vav1+ mice revealed significantly increased percentages of CD44+CD25– (DN3) and CD44+CD25+ (DN4) cells. Thus, early stages of thymopoiesis are disrupted by M-MuLV-induced leukemia, in both WT and Vav1+ mice, but the absence of Vav1 significantly affects the development of lymphomagenic thymi.

Age- and leukemia-mediated changes in the cell cycle entry of Vav1+/+ and Vav1–/– thymocytes. While the differentiation state of WT and Vav1–/– thymocytes in adult mice have long been known to be distinct,10 the partition of thymocytes of different developmental stages during the newborn period is not known. This is of importance in the context of the present studies because the mice were infected with M-MuLV at 3 d of age. Furthermore, given that M-MuLV infection targets proliferating cells, it was of interest to assess the cell cycle entry of different thymocyte populations. The percentage of DP thymocytes slightly decreased in WT mice between 3 d of age (the time point of M-MuLV inoculation) and 2 mo of age (Fig. 5A) whereas it was not statistically different in Vav1–/– mice. While the presence of SP4 and SP8 thymocytes augmented with age, they remained significantly lower in Vav1–/– than WT mice.

The entry of thymocytes into cell cycle, was monitored as a function of Ki67 expression, a protein upregulated during mid G1 phase. The percentage of Ki67+ cells within the DP thymocyte subset was not modulated by either age or the presence of Vav1 (Fig. 5A). The percentages of Ki67+ DN cells decreased with age but this phenomenon was observed in both WT and Vav1–/– mice. Notably, within the SP8 population, the relative proportion of Ki67+ cells was higher during the newborn period, with greater than 50% of this subset expressing Ki67 in neonatal Vav1–/– mice. However, the total numbers of Ki67+ SP8 thymocytes were still lower in Vav1–/– mice due to the relative paucity of this population. Almost identical data were obtained in the SP4 population. Importantly, the increased
Interestingly though, we did not observe any increase in DP cells in lymphomagenic thymi of adult mice (Fig. 3), suggesting that the virus did not target this population, or, alternatively, that infected cells underwent differentiation during the transformation process. SP4 cells, which represented the most abundant population in lymphomagenic thymi from both genotypes, were only rarely Ki67 + (Fig. 5B). Given that MuLV infection requires mitosis, these data strongly suggest it is not the SP4 subpopulation, which is the largest population present in both genotypes. Interestingly though, we did not observe any increase in DP cells in lymphomagenic thymi of adult mice (Fig. 3), suggesting that the virus did not target this population, or, alternatively, that infected cells underwent differentiation during the transformation process. SP4 cells, which represented the most abundant population in lymphomagenic thymi from both genotypes, were only rarely Ki67 + (Fig. 5B). Given that MuLV infection requires mitosis, these data strongly suggest it is not the SP4

Thymocytes from control or M-MuLV infected mice were stained as described in Figure 3. Within the SP4 gate (CD4+CD8-), TCRβ expression was assessed. The mean percentages ± SEM of SP4 cells expressing TCRβ are presented. Data were evaluated using Student’s t-test. TCRβ expression within the SP4 thymocyte subset in infected Vav1-/- mice was significantly lower than that detected in uninfected WT mice, uninfected Vav1-/- mice and WT infected mice. p < 0.05 compared with non infected WT mice (1), compared with WT mice (2) and compared with non infected Vav1-/- mice.

Figure 3. Thymocyte populations in M-MuLV infected mice. (A) Flow cytometry analysis of thymi from control and M-MuLV infected mice. Cells were stained with anti-CD4 and anti-CD8 antibodies to distinguish CD4-/CD8- (DN), CD4+/CD8- (DP), CD4+/CD8+ (CD4+) and CD4-/CD8+ (CD8+) populations. (B) Percentages of DN, DP, CD4+ and CD8+ from representative populations of mice (Vav1+/- control (n = 4), Vav1-/- control (n = 6), Vav1+/- M-MuLV (n = 9), Vav1-/- M-MuLV (n = 9)). The numbers in brackets reflect the mice whose plots are depicted in (A). (C) Representative histograms showing TCRβ expression in the CD4+/CD8- subset of different mice populations. Data were evaluated using Student’s t-test: *p < 0.05; **p < 0.01; ***p < 0.001.
In this report, we investigated whether a protein that plays an essential role in lymphopoiesis also influences leukemogenesis. Vav1 strongly affects the T cell compartment without modulating other lineages and as such, it was of interest to selectively induce T cell leukemias. To this end, we used the M-MuLV retrovirus that lacks oncogenes and induces T cell lymphomas with a latency of 3–4 mo. Here, we report that the presence of Vav1 regulates M-MuLV-induced T cell leukemogenesis.

**Vav1**$^{+/+}$ mice infected with M-MuLV develop the typical disease, characterized by a decrease in hematocrit, a modest enlargement of the thymus and a significant splenomegaly (Figs. 1 and 2 and reviewed in ref. 17 and 20–24). At the cellular level, leukemic cells predominantly expressed markers associated with T cell maturation such as CD3 and TCR$^\beta$ (Figs. 3 and 4). Notably, in the absence of Vav1, infection with M-MuLV resulted in leukemias characterized by higher hematocrits, massive thymus enlargement and a more modest splenomegaly. Furthermore, the leukemic phenotypes in the thymus as well as the periphery differed; with a significantly more immature phenotype in Vav1$^{-/-}$ as compared with WT mice.

**Induction of tumors by M-MuLV presumably results from infection of a target cell and a series of subsequent tumor progression events.** Target cells for M-MuLV are early cells committed to the T cell lineage and they differentiate to various stages in T-cell differentiation before the final transforming event. In this report, we investigated whether a protein that plays an essential role in lymphopoiesis also influences leukemogenesis. Vav1 strongly affects the T cell compartment without modulating other lineages and as such, it was of interest to selectively induce T cell leukemias. To this end, we used the M-MuLV retrovirus that lacks oncogenes and induces T cell lymphomas with a latency of 3–4 mo. Here, we report that the presence of Vav1 regulates M-MuLV-induced T cell leukemogenesis. Vav1$^{-/-}$ mice infected with M-MuLV develop the typical disease, characterized by a decrease in hematocrit, a modest enlargement of the thymus and a significant splenomegaly (Figs. 1 and 2 and reviewed in ref. 17 and 20–24). At the cellular level, leukemic cells predominantly expressed markers associated with T cell maturation such as CD3 and TCR$^\beta$ (Figs. 3 and 4). Notably, in the absence of Vav1, infection with M-MuLV resulted in leukemias characterized by higher hematocrits, massive thymus enlargement and a more modest splenomegaly. Furthermore, the leukemic phenotypes in the thymus as well as the periphery differed; with a significantly more immature phenotype in Vav1$^{-/-}$ as compared with WT mice.

Discussion

**Phenotype of peripheral leukemic cells in Vav1$^{+/+}$** and Vav1$^{-/-}$ mice. M-MuLV-induced leukemias are first produced in the thymus but there is also a peripheral involvement during later stages of the disease. In order to characterize the phenotype of lymphomagenic cells in the periphery, we studied the expression of several cell markers in splenocytes from M-MuLV-inoculated mice. In WT as well as Vav1$^{+/+}$ leukemic mice, there was an expected decrease in the percentage of CD19$^+$ B cells due to the presence of leukemic cells. As Vav1$^{-/-}$ mice have decreased percentages of peripheral T cells under normal conditions, the relative percentage of CD19$^+$ cells filling this niche was initially increased. Somewhat surprisingly though, there was a decreased percentage of CD3$^+$ cells in leukemic Vav1$^{+/+}$ mice (Fig. 6A). As leukemic cells generally lacked TCR$^\beta$ expression Vav1$^{+/+}$ mice (Fig. 3), we assessed whether these peripheral TCR$^\beta$ CD3$^+$ cells expressed CD4 or CD8 lineage markers. Indeed, there were more than 4-fold increases in both CD3 CD4$^+$ and CD3 CD8$^+$ cells in leukemic Vav1$^{+/+}$ mice (Fig. 6B). Interestingly, the increase in these immature CD3$^+$ cells was modest in WT mice with leukemias (2–4% to approximately 8%; Fig. 6B). Furthermore, mature CD3 CD4$^+$ and CD3 CD8$^+$ were not significantly increased in leukemic WT mice and in fact, were decreased in the Vav1$^{+/+}$ mice. Thus, in Vav1$^{+/-}$ mice with leukemias, splenocytes as well as thymocytes harbor an immature CD3$^+$ T cell phenotype. Altogether, CD3$^+$ leukemias were significantly decreased in Vav1$^{+/+}$ mice as compared with WT mice following infection with M-MuLV.

**Figure 4.** Impaired thymocyte development in Vav1$^{+/+}$ M-MuLV mice. (A) Flow cytometric analysis of thymi from control and M-MuLV infected mice. Cells were stained with CD44 and CD25 antibodies to distinguish DN1 (CD44$^+$/CD25$^-$), DN2 (CD44$^+$/CD25$^+$), DN3 (CD44$^-$/CD25$^+$) and DN4 (CD44$^-$/CD25$^-$) subsets within the CD4 CD8 population. (B) Percentages of DN1, DN2, DN3 and DN4 from representative populations of mice (Vav1$^{+/+}$ control (n = 6); Vav1$^{+/-}$ M-MuLV (n = 4); Vav1$^{+/-}$ M-MuLV (n = 9)). The numbers in brackets reflect the mice whose plots are depicted in (A). Data were evaluated using Student’s t-test: *p < 0.05; **p < 0.01; ***p < 0.001.
immature population in the thymus is the DN subset, which is subdivided into different stages: CD44+/CD25- (DN1), the CD44+/CD25+ (DN2) stage during which TCRβ rearrangements are initiated, the CD44-/CD25+ (DN3) stage associated with initial CD3 expression and selection for productive TCRβ rearrangements, followed by the CD44-/CD25- (DN4) stage of the TCRβ locus. The expression of a functional pre-TCR complexes leads to the DN4 stage and DP cells, expressing the CD4 and CD8 coreceptors, undergo TCRα rearrangements and express a mature TCRαβ complex. After positive and negative selection these cells become SP thymocytes with the maximal expression of CD3. The CD4+ thymocyte population increased in mice developing M-MuLV-induced leukemias. Importantly though, in Vav1-/- mice, leukemogenesis resulted in a massive accumulation in DN cells. Moreover, the DN population was altered in both mice strains, suggesting that these cells may represent a preleukemic state. As DN4 cells were the major DN population in infected Vav1-/- thymi, it is likely that leukemic cells overpassed the Vav1 requirement at the DN3 to DN4 transition (Fig. 4) or alternatively, were infected at that stage as they show a proliferative burst.30,31

Because the thymocyte population that increased in lymphomagenic thymi was CD4+, we compared the expression of two T cell differentiation markers in leukemic Vav1+/+ and Vav1-/- CD4+ cells; CD3 and TCRβ. We found that CD4+ cells derived from leukemic Vav1-/- mice lacked expression of TCRβ (Fig. 3 and Table 1), even if CD4 was expressed at high levels. In agreement with the thymus data, the vast majority of peripheral leukemic cells in Vav1-/- mice were CD3-. We favor a model in which, in the absence of Vav1, the pre-leukemic T cells fail to properly differentiate keeping their immature phenotype.

**Figure 5.** Cell cycle entry of different thymocyte populations. Thymocytes were stained with the corresponding antibodies to identify CD4-/CD8- (DN), CD4+/CD8+ (DP), CD4-/CD8- (SP4) and CD4+/CD8+ (SP8) cells and with an anti-Ki67 antibody to analyze cell cycle entry. (A) The total percentages of cells and the percentages of Ki67+ cells in the different populations are shown in 3-d old (white bars) and adult (black bars) mice of both genotypes. (B) Comparative analysis of Ki67 expression in the different populations between Vav1-/- and wild-type mice. Data represent the mean percentages ± SEM of three independent experiments with n = 3 mice per group. Data were evaluated using Student’s t-test: *p < 0.05; **p < 0.01; ***p < 0.001.
the majority of M-MuLV-induced leukemias were of the CD4 phenotype. Some ATL, as well as mice harboring the Tax gene of HTLV-1, present with an immature CD4-CD8- phenotype. It will be of interest to assess Vav1 expression in these leukemias, which could correlate with the developmental status of the leukemic cells.

All together our data suggest that the proteins involved in T cell differentiation also regulate the development of T cell leukemias. Induction of tumors by a retrovirus results from infection of a target cell and a series of subsequent tumor progression events. The data presented here suggest that the target cells wherein M-MuLV promotes tumor formation differ in the presence and absence of Vav1. In Vav1 deficient mice, impaired T cell development during the selection processes favors the emergence of a different tumor phenotype.

Materials and Methods

Mice. Vav1-/- mice in the 129 SV background, a generous gift from Dr. V. Tybulewicz, have been previously described in reference 12, and were maintained under the same conditions as 129 SV mice. All animal experiments were performed according to the guidelines and regulations of the Centre National de la Recherche Scientifique.

Virus inoculation and clinical evaluation of mice. Vav1-/-, Vav1+/+ and 129 SV mice, 18 to 72 h old, were inoculated intraperitoneally with 10^5 focus forming units (FFU) of M-MuLV in 50 μL as previously described in reference 20. Mice were monitored for gross organ enlargement by palpation under Forene® (isoflurane, Abbott France) anesthesia. Hematocrits, expressed as the percentage of erythrocytes in the blood volume, were measured in retroorbital vein blood samples collected in heparinized capillary tubes. Fifty days after infection, hematocrits were monitored regularly at approximately 20-d intervals. After sacrifice of moribund animals, spleens were weighed and thymic size was scored from normal, to clearly enlarge (medium), to invading the whole thoracic cavity (large).
Immunophenotyping and flow cytometry analyses. Splenocytes and thymocytes were stained with the appropriate conjugated αCD8, αCD4, αCD3, αCD25, αCD44, Ki-67, TCRβ (PharMingen, San Diego, CA), αCD3 and αCD19 (ImmuneTech, Marseille, France) mouse monoclonal Abs, as indicated. Stained cells were analyzed by flow cytometry using a FACSCalibur (Becton Dickinson, San Jose, CA) and analyses were performed with CellQuest (Becton Dickinson) or Flowjo (Tree Star, Ashland, Oregon) software as previously described in reference 36 and 37.

Statistical analysis. All results were analyzed by an unpaired Student’s t-test.

Disclosure of Potential Conflicts of Interest No potential conflicts of interest were disclosed.
