HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Angiogenesis and the tumor space-time continuum.

Tumors invade space through cancer cells proliferation and tumor mass expansion. Tumor growth is maintained over time using the cancer stem cell pool, which is the cell population with self-renewal potential. In their paper Conley et al. provide evidence that anti-angiogenic agents increase cancer stem cells through the generation of tumor hypoxia (1). These findings are in accordance with those demonstrating that hypoxia induces stem cell markers expression in cancer cells (2-4), and that anti-angiogenic therapy elicits malignant progression of tumors (5). Thus, there is now sufficient evidence to reconsider the role of tumor angiogenesis in cancer progression. Tissues need nutrients and oxygen for growth and tumor behaves as other tissues. This is the classical view, in which, according to Folkman, the role of tumor angiogenesis fulfills the function of normal vessels that is to deliver oxygen and metabolites and to remove waste products. However, tumor vessels are abnormal and fail to fulfill these functions. Therefore, tumors have naturally chronic and cyclic hypoxic regions. This is a paradoxical consequence of tumor angiogenesis, because of its deficiencies, also generates hypoxia. In pathology, such as cancer, a defect in a physiological process does not necessarily suppress the function of the process but can generate a novel function required for disease development. Here, the other function of tumor angiogenesis is to maintain tumor growth over time via cancer stem cell increase. This dual nature of tumor angiogenesis ensures a balance between growth over space (by providing oxygen and nutrients; i.e. physiological function), and growth over time (by generating hypoxic regions that increase the cancer stem cell pool; i.e. pathophysiological
function). Hence, tumor requires both the physiological and the pathophysiological functions of tumor angiogenesis. Therefore the significance of angiogenesis is the generation of a tumor space-time continuum.
