Running title : Metabolic effects of *myo*-inositol

Keywords : *myo*-inositol ; insulin-sensitizing ; antioxidant ; fat mass ; skeletal muscle ; white adipose tissue

Abstract

Type 2 Diabetes is a complex disease characterized by a state of insulin resistance in peripheral tissues such as skeletal muscle, adipose tissue or liver. Some inositol isomers have been reported to possess insulin-mimetic activity, and to be efficient in lowering blood glucose level. The aim of the present study was to assess in mice the metabolic effects of a chronic treatment with *myo*-inositol, the most common stereoisomer of inositol. Mice given *myo*-inositol treatment (0.9 or 1.2mg.g⁻¹ per day, 15 days, orally or intraperitoneally) exhibited an improved glucose tolerance due to a greater insulin sensitivity. Mice treated with *myo*-inositol exhibited a decreased white adipose tissue accretion (-33%, p<0.005) compared with controls. The decrease in white adipose tissue deposition was due to a decrease in adipose cell volume (-33%, p<0.05) while no change was noticed in total adipocyte number. In skeletal muscle, *in vivo* as well as *ex vivo* *myo*-inositol treatment increased protein kinase B/Akt phosphorylation under baseline and insulin stimulated conditions suggesting a synergistic action of *myo*-inositol treatment and insulin on proteins of the insulin signalling pathway. *Myo*-inositol could therefore constitute a viable nutritional strategy for the prevention and/or treatment of insulin resistance and type 2 diabetes.

Abbreviations :

ANOVA, analysis of variance

AMPK, 5'-AMP activated protein kinase

AU, arbitrary unit

BMI, body mass index

BSA, bovine serum albumin

BW, body weight

DTT, dithiothreitol

EIA, enzyme immunoassay

EDTA, ethylenediaminetetraacetic acid

GLUT4, glucose transporter 4

GPI, glycosylphosphatidylinositol

GTT, glucose tolerance test

HOMA-IR, homeostasis model assessment of insulin resistance

IgG, immunoglobulin G

IL-1, interleukin 1

IL-6, interleukin 6

IL-8, interleukin 8

IRS, insulin receptor substrate

ITT, insulin tolerance test

K_{ITT}, glucose disappearance rate during ITT

KRB, Krebs ringer bicarbonate buffer

LD50, lethal dose 50%

MEM, minimum essential medium

NEFA, non-esterified fatty acids

PKB/Akt, protein kinase B/Akt

PI3K, phosphoinositide-3-kinase

PIP₂, phosphatidyl inositol-4,5-bisphosphate

ROS, reactive oxygen species

SDS-PAGE, sodium dodecyl sulfate polyacrylamide gel electrophoresis

sdLDL, small dense lipoproteins

TBARS, thiobarbituric acid reactive substances

TBST, Tris-Buffered Saline - Tween 20

TNF- α , Tumor necrosis factor alpha

WAT, white adipose tissue

pWAT, parametrial WAT

rWAT, retroperitoneal WAT

scWAT, subcutaneous WAT

Introduction

Type 2 diabetes mellitus is a complex disease characterized by a state of insulin resistance of peripheral tissues such as skeletal muscle, white adipose tissue and liver. In order to manage diabetes mellitus blood glucose must be controlled, especially in postprandial condition since its regulation implies, in this case, the actions of insulin in suppressing hepatic glucose production and triggering glucose uptake in skeletal muscle and adipose tissue. Inositol, formerly referred to as vitamin B7, stands for 1,2,3,4,5,6-cyclohexanehexol and includes nine distinct stereoisomers (named *allo*-, *D-chiro*-, *L-chiro*-, *cis*-, *epi*-, *muco*-, *myo*-, *neo*-, and *scyllo*-inositol) through epimerization in hydroxyl group configuration (see **Supplementary Fig. 1**). In addition to various biological functions for the treatment of diseases such as depression, panic disorder or polycystic ovary syndrome (1–5), some inositol derivatives exhibit insulin-mimetic activity, and are efficient in lowering blood glucose level. For instance, administration of *D-chiro*-inositol to diabetic rats, rhesus monkeys, mice and humans increases glucose disposal and improves insulin sensitivity (1,6–9). D-pinitol, the 3-O-methylated form of *D-chiro*-inositol, is also one of the naturally occurring inositol derivatives. D-pinitol from soybeans or *Bougainvillea spectabilis* leaves has also been reported to reduce blood glucose level in streptozotocin-induced diabetic rats and in patients with diabetes mellitus (10–14). *D-chiro*-inositol and D-pinitol are rare inositol derivatives, whereas among all the nine inositol isomers, *myo*-inositol is the only one to be widely distributed in tissues and foodstuffs (15). Since *myo*-inositol can be converted to *D-chiro*-inositol in insulin sensitive tissues, namely skeletal muscle, adipose tissue and liver (7,16,17), *myo*-inositol has been mainly regarded as a nutritional source of *D-chiro*-inositol. Ortmeyer demonstrated that administration of a high dose of *myo*-inositol ($1.5\text{g}\cdot\text{kg}^{-1}$) to diabetic monkeys was efficient in lowering blood glucose level (18). Recent studies demonstrated that oral administration of *myo*-inositol is able to improve glucose tolerance and trigger skeletal muscle GLUT-4 translocation in C57/BL6 mice, suggesting an improvement of insulin sensitivity (19). However, *in vitro* studies of glucose uptake on rat L6 myotubes (20) as well as some experiments on rodents yielded conflicting results (6). To date the effect of a chronic treatment with *myo*-inositol, which would be more compatible with a therapeutic-targeted strategy for diabetes mellitus prevention or care, remains to be documented. Hence, we tested in the present study, the effect of fifteen days of treatment with *myo*-inositol on insulin sensitivity in female CD-1 Swiss mouse.

Methods & Materials

Chemicals and antibodies

Myo-inositol, was purchased from Sigma Aldrich, (Saint Quentin Fallavier, France), recombinant Human insulin (100 UI/ml, Actrapid®) was from Novo Nordisk, (La Défense, France). Anti-Phospho-Akt 1/2/3 rabbit IgG (7985R) and anti-Akt 1/2/3 rabbit IgG (8312) antibodies were purchased from Santa Cruz Biotechnology (Santa Cruz, Heidelberg, Germany), anti-tubulin mouse IgG antibody was from Sigma Aldrich, anti-mouse IgG and anti-rabbit IgG antibodies were from BioRad (Marnes-la-Coquette, France). Super Signal® West Pico Chemiluminescent Substrate and Restore™ Western Blot Stripping Buffer were obtained from Thermo Scientific (Perbio, Brebières, France). Other chemicals were obtained from Sigma Aldrich when no origin is specified.

Animals

Female CD-1 Swiss mice (30-35g) were purchased from Janvier SA (Le Genest-Saint-Isle, France) and housed in an air-conditioned room with a controlled environment of $21 \pm 0.5^{\circ}\text{C}$ and 60-70% humidity, under a 12h light/dark cycle (light on from 07:00h to 19:00h) with free access to food (13,4 kJ/g, 65% carbohydrates, 11% fat, 24% proteins (w/w), AO3, SAFE, Augy, France) and water. All experiments were carried out according to the guidelines laid down by the French Ministère de l'Agriculture (n° 87-848) and the E.U. Council Directive for the Care and Use of Laboratory Animals of November 24th, 1986 (86/609/EEC).

Myo-inositol treatment

Sixty mice were randomly assigned to receive daily intraperitoneal injection of either a saline solution (NaCl 0.9%, w/v) or *myo*-inositol ($1.2 \text{ mg.g}^{-1} \text{ BW}$) for 15 days. Food intake and body weight were measured twice weekly. Food consumption was calculated as the difference between the amount given and that removed from the cage. A second set of mice (n=20) was given *myo*-inositol in drinking water (6 g.L^{-1}) for 15 days. Water consumption was measured to assess daily *myo*-inositol intake.

Metabolic challenges

Glucose tolerance test: After an overnight fast, animals were injected intraperitoneally with 1 g.kg^{-1} body weight of D-glucose in sterile water. Blood glucose was measured before and 15, 30, 60 and 90 min after injection. On an independent group of animals (n=5), 200 μL of

blood were collected by retro-orbital sinus puncture from each mouse into a heparinized microcentrifuge tube, 30 min after glucose load in order to measure plasma insulin level at the hyperglycaemic phase of the test. Blood was centrifuged 2 min at 3500g (4°C) to prepare plasma. Plasma samples were snap frozen in liquid nitrogen and stored at -20°C until insulin assay.

Insulin tolerance test: After an overnight fast, animals were injected intraperitoneally with 0.30 UI.kg⁻¹ BW of recombinant human insulin. Blood glucose was measured before and 15, 30, 60 and 120 min after insulin injection. The glucose disappearance rate for ITT (K_{ITT} ; %·min⁻¹) was calculated using the formula given by Lundbeak (1962) (21): $K_{ITT} = 0.693 \times 100 / t_{1/2}$ where $t_{1/2}$ was calculated from the slope of the plasma glucose concentration, considering an exponential decrement of glucose concentration during the 40 min after insulin administration (22).

Insulin secretion test: L-arginine induced insulin secretion.

After an overnight fast, animals were injected intraperitoneally with 1 g.kg⁻¹ BW of L-arginine in saline and blood was withdrawn at 0, 2 and 5 min after injection in heparinized microtubes. Blood was centrifuged 2 min at 3500g (4°C) to prepare plasma. Plasma samples were snap frozen in liquid nitrogen and stored at -20°C until insulin assay.

Sacrifice and tissue dissection

The body weight and body length were measured and mice were then sacrificed by cervical dislocation. Blood (750µL) was collected by heart puncture on heparinized tube, centrifuged 2 min at 3500 g to prepare plasma. Plasma samples were snap frozen in liquid nitrogen and stored at -80°C until analysis. Liver, heart, kidneys, tibialis and gastrocnemius muscles, parametrial, retroperitoneal and subcutaneous inguinal white adipose tissue (WAT) were dissected out according to anatomical landmarks, weighed to the nearest milligram, snap frozen in liquid nitrogen and stored at -20°C.

Cellularity study: Measurement of adipocyte size and number

Preparation of adipose tissue for determination of cell size was performed essentially as described by Etherton, Thompson & Allen (1977) (23). Briefly, 30-40 mg of parametrial WAT were immediately fixed in osmium tetroxide and incubated at room temperature for 96h and then adipose cell size was determined by a Beckman Coulter Multisizer IV with a 400 µm aperture. The range of cell sizes that can effectively be measured using this aperture is 20–240 µm. The instrument was set to count 1,000 particles, and the fixed-cell suspension was diluted

so that coincident counting was <10%. Cell-size distributions were drawn from measurement of at least 12,000 cell diameters per animal. DNA content in parametrial WAT was measured, after delipidation of the samples, by a standard fluorimetric method using bisbenzimidazole and calf thymus DNA as standard (24).

Isolation of adipocytes

Five mice of each group were killed by cervical dislocation, parametrial and retroperitoneal fat pads were dissected out, pooled and the adipocytes were isolated. Adipose tissue was weighed, minced and digested in 7 ml of Krebs Ringer Bicarbonate (KRB, pH 7.40) buffer containing 6 mM glucose, 1% (w/v) fatty acid-free bovine serum albumin (BSA) and 1.5 mg.ml⁻¹ collagenase (type II, C6885, Sigma Aldrich). The vial was shaken (40 cycles.min⁻¹) at 37°C for 60 min. The resulting cell suspension was filtered through a nylon mesh (250 µm) and washed three times with KRB buffer containing 4% fatty acid-free BSA. Then adipocytes were resuspended in KRB containing 4% fatty acid-free BSA and counted in a hemacytometer.

Lipogenesis assay

Lipogenesis was measured in mouse isolated adipocytes as the incorporation of [¹⁴C]-acetate into total lipids as previously described (25). Briefly, aliquots (100 µl) of cell suspension were incubated in MEM medium containing 1% fatty acid-free BSA and 1 µCi of [¹⁴C]-acetate for 4 h at 37°C with gentle shaking (40 cycles.min⁻¹). Total lipids were extracted using Dole's extraction fluid (isopropanol/heptane/H₂SO₄ 1N, 40/10/1, v/v/v) and [¹⁴C] was detected by liquid scintillation counting.

Lipolysis

Aliquots of the cell suspension (100 µl) were distributed in 2 ml-polystyrene vials containing KRB buffer 4 % BSA with or without isoproterenol hydrochloride (5 µM). Adipocytes were incubated at 37°C with gentle shaking (40 cycles.min⁻¹) for one hour. The reaction was stopped by placing vials on melting ice. The floating adipocytes were discarded by aspiration and lipolysis was quantified by measuring the release of extracellular glycerol using a kit (Glycerol assay, R-Biopharm, Saint Didier aux Monts d'Or, France).

Biochemical measurements

Fasting and non-fasting blood glucose levels were measured with a glucometer (Accu Check

Performa, Roche diagnostic, Meylan, France). The plasma insulin level was determined with mouse insulin EIA kit (SpiBio, Montigny-le-Bretonneux, France) according to the manufacturer's instructions. The homeostasis model assessment of insulin resistance (HOMA-IR) was calculated using glucose and insulin concentrations obtained after 16 h of food withdrawal, using the following formula: fasting blood glucose (mg.dl⁻¹) × fasting insulin (μU.ml⁻¹)/405. Plasma total cholesterol, triacylglycerols and non-esterified fatty acid (NEFA) levels were measured with the following commercial kits, Cholesterol RTU (bioMérieux, Marcy-l'Etoile, France), Triglyceride PAP (bioMérieux) and NEFA-C (WAKO, Sobioda, Montbonnot, France) according to manufacturer's recommendations. Plasma adiponectin and leptin concentrations were determined with enzyme immuno assays (Cayman Chemicals, distributed by SpiBio) according to the manufacturer's guidelines. All assays were performed at least in duplicates. The muscle and hepatic lipids were extracted using the procedure developed by Folch (26) using Chloroform-Methanol (2:1, v/v) and total lipid content was estimated gravimetrically.

Plasma total antioxidant activity

The total plasma antioxidant activity was measured as described by Koracevic et al. (2001) (27). Briefly, the assay measured the capacity of 10 μl of plasma to inhibit the production of thiobarbituric acid reactive substances (TBARS) from sodium benzoate under the influence of the free oxygen radicals derived from Fenton's reaction. A solution of 1 mM uric acid was used as standard and results were expressed as mM equivalent uric acid.

In vivo and ex vivo insulin stimulation

In vivo insulin stimulation : To further explore insulin signalling in skeletal muscle, control and *myo*-inositol mice were randomly assigned to receive either saline or insulin (0.75 UI.kg⁻¹ BW, i.p.) 30 min before sacrifice. Mice were killed by cervical dislocation, gastrocnemius muscle was rapidly dissected out, blotted dry and snap frozen in liquid nitrogen.

Ex vivo insulin stimulation: To decipher whether *myo*-inositol was able to directly act on muscle, we performed an *in vitro* incubation of skeletal muscle with *myo*-inositol and *in vitro* insulin stimulation. Mice were killed by cervical dislocation, gastrocnemius were rapidly dissected out bilaterally and chopped into small pieces with a scalpel. Muscle pieces were incubated in 3 ml of MEM medium containing insulin (100 nM) and *myo*-inositol (1mM), *D*-*chiro*-inositol (1mM) or mannitol (1mM) as a control. Muscles were incubated for 15 min at 37°C, blotted dry and snap frozen in liquid nitrogen.

Immunoblotting – insulin induced phosphorylation of PKB/Akt in skeletal muscle

Gastrocnemius was homogenised in standard lysis buffer (20 mM Tris-HCl, 138 mM NaCl, 2.7 mM KCl, 1 mM MgCl₂, 5% Glycerol and 1% Nonidet P40) supplemented with protease and phosphatase inhibitors (5 mM EDTA, 1 mM Na₃VO₄, 20 mM NaF, 1 mM DTT, Protein inhibitor cocktail, Sigma Aldrich). 60µg of tissue lysate soluble fraction proteins were boiled in Laemmli buffer and separated by 10% sodium dodecyl sulfate – polyacrylamide gel electrophoresis (SDS-PAGE). After transfer to a nitrocellulose membrane, and aspecific sites blockage with Bovine Serum Albumin (BSA) 5% in TBST (10 mM Tris-HCl at pH 8.0, 150 mM NaCl and 0.05% Tween-20), Akt activating phosphorylation on serine was detected using primary anti-phospho(Ser 473)-Akt(1/2/3) antibody (1/1000e in TBST 3% BSA – Overnight, 4°C) and then secondary antibody (anti-rabbit, 1/10 000e TBST – 1h, room temperature) conjugated with horseradish peroxidase. Membranes were processed for chemiluminescence and proteins were quantitated by densitometry using Quantity One software (BioRad). In order to normalise for equal protein loading, membranes were stripped and re-blotted with anti total Akt(1/2/3) antibody and then anti- α -tubulin antibody.

Statistics

Data are expressed as means $\pm$ SD ($n < 4$) or means $\pm$ SE ($n \geq 4$). Data were analyzed using GraphPad Prism v5.0 software (GraphPad software, La Jolla, USA). Results of GTT, ITT and arginine tests were compared by two-way analysis of variance (time, treatment) followed when appropriated by posthoc Fisher PLSD tests. Simple comparisons were performed using Student's *t*-test. When appropriated, Welch's correction for inequality of variances was applied. Regression analyses were performed using linear regression. Adipocyte volume distribution curves were compared with the Kolmogorov-Smirnov two-sample test using "R" software (www.R-project.org). Differences were considered significant at the $p < 0.05$ level.

Results

Chronic treatment with myo-inositol reduced white adipose tissue accretion

To evaluate its *in vivo* activity, mice were given daily injection of *myo*-inositol (1.2 mg.g⁻¹ per day) or saline for 15 days. Biometric data for each group are shown in **Table 1**. Body weights of *myo*-inositol-treated animals were not significantly altered compared with saline-treated animals. Neither food intake nor water intake were different between saline- and *myo*-

inositol-treated animals. The mean daily food intake was 48.1 ± 0.9 and 50.5 ± 3.8 kJ per 24h for mice treated with saline and *myo*-inositol, respectively ($n=14$, $p=0.573$). Organs (liver, heart, kidneys and muscles) weights, taken as representative of lean mass, were not different between the two groups but *myo*-inositol treatment significantly reduced adiposity as evidenced by a lower adiposity index (Lee index $n=14$, $p<0.05$) and a significantly reduced fat mass accretion (-33% , $n=14$, $p<0.005$). *Myo*-inositol treatment significantly reduced accretion of intra-abdominal fat pad, that is, retroperitoneal and parametrial fat pads while no effect was noticed on sub-cutaneous fat pad, that is, inguinal fat pad (**Table 1**). Indeed, parametrial and retroperitoneal WAT masses were reduced by 38% in *myo*-inositol treated animals, while subcutaneous WAT mass remained unaltered. Of note, the fat mass loss was not associated with ectopic redistribution of lipids in liver or skeletal muscles as evidenced by the measurement of tissues lipid contents (**Table 2**).

Effect of chronic treatment with myo-inositol on plasma metabolites

The plasma metabolites levels for each group are shown in **Table 2**. The plasma levels of triacylglycerols or cholesterol were not affected by *myo*-inositol treatment. However, plasma level of non-esterified fatty acids was sharply reduced in *myo*-inositol mice (-37% , $n=14-16$, $p<0.001$). Fasting blood glucose level was not significantly different between the two groups ($n=14$, $p=0.41$) while fed plasma glucose level of *myo*-inositol mice was significantly lower than that of control mice (-10% , $n=14$, $p<0.05$). The homeostasis model assessment of insulin resistance (HOMA-IR) was calculated as a clinical parameter for the insulin resistance, from the values of blood glucose and insulin plasma levels. The HOMA-IR index for *myo*-inositol group was similar to that of control group ($n=6$, $p=0.89$). In good agreement with the reduction of fat accretion observed in *myo*-inositol mice, we noticed a significant decrease in plasma leptin concentration (-63% , $n=9-10$, $p<0.05$). Plasma leptin concentration was negatively correlated with total white adipose tissue mass ($n=19$, $r^2=0.741$, $p<0.0001$, see **supplementary Fig. 2**). In contrast, no difference in plasma adiponectin level was noticed between the two groups (**Table 2**). *Myo*-inositol treated mice exhibited a higher total antioxidant plasma activity than control mice ($+46\%$, $n=9-10$, $p<0.005$, **Table 2**).

Chronic treatment with myo-inositol improved glucose tolerance and insulin sensitivity

To get an insight into glucose homeostasis, glucose, insulin and arginine challenges were performed in *myo*-inositol and saline-treated mice. Glucose tolerance test showed that the glucose load induced a marked and transient rise in blood glucose level with a complete

normalisation 90 min after injection (**Fig. 1A**). Under the same conditions, *myo*-inositol mice exhibited a lower blood glucose level than control mice at 15 and 30 min after glucose injection (n=10, p<0.05 and p<0.001, respectively), suggesting a better glucose tolerance. Consequently, the area under the curve of glycaemia was significantly lower in the *myo*-inositol mice ($11660 \pm 329 \text{ mg.dl}^{-1}.\text{min}^{-1}$) compared to control mice ($14420 \pm 873 \text{ mg.dl}^{-1}.\text{min}^{-1}$) indicating a faster glucose disposal (n=10, p<0.05). The better glucose tolerance may be attributed to either increased peripheral insulin sensitivity or improved glucose-stimulated insulin secretion. To determine whether the observed glucose tolerance was the result of greater insulin secretion, insulin was assayed during the glucose tolerance test. Baseline plasma insulin levels were not different, but insulin secretion in response to hyperglycaemia (i.e. 30 min after glucose injection) was significantly lower for the *myo*-inositol group (**Fig. 1B**, n=7, p<0.005) suggesting a better insulin sensitivity rather than a greater insulin secretion. To further measure the *in vivo* insulin response of *myo*-inositol treated mice, we performed administration of the non-glucose secretagogue arginine. The acute insulin response (2 min after arginine injection) was similar in the two groups (**Fig. 1C**) excluding difference in insulin secretion capacity. The results of the insulin tolerance test (ITT) are shown in **Fig. 1D**. Insulin administration (0.3 UI.kg^{-1}) triggered a significantly (p<0.01) larger hypoglycaemic response in *myo*-inositol mice (-45% in blood glucose level) compared to control mice (-25%). The glucose disappearance rate (K_{ITT}) was two-fold higher in *myo*-inositol than in control mice (10.3 ± 1.2 versus $5.8 \pm 1.6 \text{ \%.min}^{-1}$, n=10, p<0.05). Taken together, the results of the metabolic challenges indicated a better glucose tolerance due to a better insulin sensitivity of *myo*-inositol treated mice. Interestingly, the glucose disappearance rate (K_{ITT}) that reflects insulin sensitivity, was negatively correlated with central fat mass (**Fig. 2**, $r=-0.718$, p<0.002). Hence, the reduction in fat mass accretion could be a major determinant of the long term insulin-sensitizing effect of *myo*-inositol treatment.

Chronic treatment with myo-inositol potentiated insulin signalling in skeletal muscle

To get an insight into insulin signalling pathway, phosphorylation of PKB/Akt was explored in skeletal muscle after insulin stimulation *in vivo*. Results from immunoblotting (**Fig. 3A**) showed a twofold increase in phosphorylation level of PKB/Akt in the gastrocnemius muscle of control mice in response to insulin (+66%, p<0.05). *Myo*-inositol treatment increased PKB/Akt phosphorylation under baseline conditions (+66% from unstimulated control, p<0.05) as well as in response to insulin (+166% from unstimulated control, p<0.05) suggesting an additive effect of insulin and *myo*-inositol. Some authors (19,28) suggested that

in vivo, *myo*-inositol is metabolically converted into other inositol isomers (especially *D-chiro*-inositol) which could mediate its effects on glucose metabolism. To challenge this view, mouse isolated gastrocnemius were incubated in presence of 1 mM of *myo*-inositol, *D-chiro*-inositol or mannitol (as an osmotic control) with or without insulin (100nM). *Myo*-inositol but not *D-chiro*-inositol potentiated insulin induced PKB/Akt phosphorylation on Serine⁴⁷³ in baseline as well as insulin-stimulated conditions (**Fig. 3B**) suggesting a direct action of *myo*-inositol on muscle or its conversion *in situ* to an active metabolite.

Myo-inositol is active when orally administered

We tested the effect of 15 days of oral administration of *myo*-inositol on fat accretion in mice (**Table 3**). The mean daily intake of *myo*-inositol was $0.90 \pm 0.04 \text{ mg.g}^{-1}$ per day. Oral administration of *myo*-inositol decreased intra-peritoneal fat accretion (**Table 3**). The 2-way ANOVA indicated a main effect of treatment ($p < 0.05$), a main effect of WAT site ($p < 0.001$), as well as a treatment $\times$ WAT site interaction ($p < 0.05$). Indeed, parametrial WAT, retroperitoneal WAT and subcutaneous WAT weights were decreased by 34% ($p < 0.05$), 33% ($p < 0.05$) and 47% ($p < 0.01$), respectively in *myo*-inositol animals while no difference was noticed for muscle or organ weights. *Myo*-inositol 0.9 mg.g^{-1} per day orally significantly reduced fat accretion in mice showing that *myo*-inositol was active after oral administration as well (**Fig. 4A**). *Myo*-inositol treated mice exhibited a lower white adipose tissue accretion relative to their body mass than saline treated mice (**Fig. 4B**). Indeed, the slope of the linear regression of fat accretion in saline treated mice was $(226.2 \pm 36.6 \text{ mg WAT/g BW, } r^2=0.65)$ while it was $(128.6 \pm 30.5 \text{ mg WAT/g BW, } r^2=0.45)$ in *myo*-inositol treated mice (significant difference between the slopes, $p=0.04$, $n=24$ in each group). To analyze whether changes in WAT accretion resulted from a reduction in the number of adipocytes, a decreased triglyceride accumulation in adipocytes or both, we performed a cytological analysis of parametrial WAT pad. The distribution frequencies of adipocyte volume for saline or *myo*-inositol treated mice are shown in **Fig. 4C,D**. A significant shift leftward was observed in frequency distribution of adipocyte volumes of mice treated with *myo*-inositol compared with control animals. The cellular characteristics of parametrial WAT in control and *myo*-inositol-fed mice are shown in **Table 4**. The reduction of WAT accretion resulted from a reduction in the volume of adipocytes (*i.e.* hypotrophia) (see **supplementary Fig. 3**) rather than from a decrease in the total number of adipocytes per fat pad (*i.e.* hypoplasia). Indeed, mean adipocyte diameter was reduced by 13% in *myo*-inositol treated mice ($n=9-10$, $p < 0.05$).

resulting in a 33% decrease in adipose cell volume ($n=8-10$, $p<0.01$). The total number of adipocytes per parametrial fat pad, calculated from cell weight, failed to show any difference in the total number of adipocytes between *myo*-inositol and control mice. As DNA amount reflects adipose cell number more accurately than any other method, we performed DNA assay in parametrial WAT. No difference was observed in DNA content, excluding a decrease in the total number of adipocytes in pWAT pads. To get an insight into the mechanisms of *myo*-inositol action on adipose cells, we measured both the lipolytic response to catecholamines and *de novo* lipogenesis. To this end, mice were fed for 15 days with *myo*-inositol in drinking water (6g.L^{-1}) and lipogenesis and lipolytic activities were measured on adipocytes isolated from parametrial fat pad of control and *myo*-inositol fed mice (**Fig. 4E,F**). Lipolysis and lipogenesis measured on isolated adipose cells failed to show any difference between the 2 groups.

Discussion

In the present study, *myo*-inositol was evaluated for its putative effects on glucose homeostasis and insulin sensitivity in female mice. To this end, female CD1 mice were given daily injection (1.2 mg kg^{-1}) or were fed with *myo*-inositol (0.9 mg.kg^{-1}) for 15 days. Our results demonstrate that intraperitoneally as well as orally administered *myo*-inositol improved glucose tolerance, enhanced insulin sensitivity and decreased adipose tissue accretion in mice. Of note *myo*-inositol treatment did not promote insulin secretion by pancreatic beta-cells, as evidenced by arginine challenge. Various inositol derivatives, such as *D-chiro*-inositol (9,29) and D-pinitol (11,13) exhibited an insulin-mimetic activity, and were efficient in lowering blood glucose level. However, they remained rare compounds in contrast with *myo*-inositol which is the most common stereoisomer of inositol. The primary naturally occurring sources of *myo*-inositol in food are inositol hexaphosphate (also referred to as phytic acid, which is widely found in fruits, vegetables, cereals, nuts and beans) and inositol-containing phospholipids (i.e. phosphatidyl-inositol) from animal and plant sources. In humans, *myo*-inositol has been successfully used in the treatment of psychiatric disorders such as depression, obsessive-compulsive disorder or panic attacks, as well as in the treatment of polycystic ovary syndrome and diabetic neuropathy (2,3,30–32). Ortmeyer et al. demonstrated that administration of *myo*-inositol to type 2 diabetic rhesus monkeys was efficient to manage blood glucose level (18). Recently, Dang et al. reported that acute oral administration of *myo*-inositol lowers plasma glucose after an oral GTT and induces GLUT4

translocation in mice skeletal muscle (19). However some *in vitro* studies and experiments on rodent yielded conflicting results. Indeed, in contrast to many inositol stereoisomers (including *D-chiro*-inositol) *myo*-inositol failed to stimulate glucose uptake in L6 muscle cells (20). Low doses ($10\mu\text{g}\cdot\text{g}^{-1}$ BW) of *myo*-inositol were reported to be inefficient for the regulation of plasma glucose level in rat with streptozotocin-induced diabetes contrary to low doses of *D-chiro*-inositol (6). Human studies also yielded conflicting results regarding its potency to improve glucose metabolism. Maeba et al. (2008) (33) showed that a *myo*-inositol chronic treatment decreased atherogenic cholesterol level (especially sdLDL) in human hyperlipidemic subjects (with or without metabolic syndrome) but a positive effect on glucose metabolism was only observed in the sub-group of hyperlipidemic subjects with metabolic syndrome. In a recent study, Corrado et al. (2011) (34) demonstrated that *myo*-inositol improved HOMA-IR in women with gestational diabetes.

We demonstrated that *myo*-inositol potentiated insulin action *in vivo* as well as *in vitro*. According to the result of the immunoblotting on PKB-Akt in mice gastrocnemius muscle, it can be presumed that *myo*-inositol treatment improves insulin sensitivity via the induction of the intracellular insulin signalling cascade at the level of this protein (PKB-Akt) and possibly even upstream in the cascade, at the level of the PhosphoInositide-3-Kinase (PI3K), whose substrate PIP_2 is produced from *myo*-inositol precursors. These results are in good agreement with data from Dang et al. (19) who demonstrated that *myo*-inositol increased GLUT-4 translocation to plasma membrane at a basal level (i.e. in absence of insulin stimulation). Our results indicated that the increased translocation of GLUT-4 to plasma membrane could be mediated through the canonical PI3K/Akt pathway. Further studies are however needed to decipher the exact mechanism of action of *myo*-inositol in muscle cells. Many authors postulated that *myo*-inositol acted on glucose homeostasis through its conversion to an active metabolite (19,34). Some studies (19,28,35) suggest that *myo*-inositol is metabolically converted into other inositol isomers or derivatives *in vivo*, in particular in *D-chiro*-inositol (DCI) or inositol phosphoglycans (IPGs). Indeed, *D-chiro*-inositol was found to be directly active *in vitro* to stimulate GLUT-4 translocation to the membrane in muscle cells, while *myo*-inositol was only active *in vivo* in mouse skeletal muscle (19,20). Moreover *myo*-inositol can be converted to *D-chiro*-inositol by a specific epimerase with a conversion rate of 7.6% and 8.8% in blood and muscle respectively (16) it is then possible that *myo*-inositol is active on glucose metabolism through its conversion to *D-chiro*-inositol. However, the underlying mechanisms of this insulin-like activity of *D-chiro*-inositol remain elusive. It has been

presumed that *D-chiro*-inositol activates PI3K and/or 5'AMP-activated protein kinase (AMPK) to stimulate GLUT-4 translocation (19). *D-chiro*-inositol increases skeletal muscle glycogen synthase activity and decreases glycogen phosphorylase activity during a euglycemic hyperinsulinemic clamp in rhesus monkeys (36). Besides, *D-chiro*-inositol was originally discovered as a component of an inositol phosphoglycan (IPG), and some data suggest that inositol phosphoglycans are second messengers of insulin action, released from GPI membrane precursors in response to insulin (28,35), (37). IPGs are able to mimic many of the insulin actions including stimulation of lipogenesis, glycogen synthesis and glucose uptake. All the natural IPGs contain a terminal inositol and both *chiro*- and *myo*-inositol isomers were found (7,28). Hence a part of the chronic *myo*-inositol treatment effect on insulin sensitivity could be due to the enhanced production of IPGs containing *myo*-inositol. Larner et al. proposed a mechanism of action for the IPGs and a new insulin signaling model including those second messengers (7,28). In this new model, a surrogate pathway for insulin signal transduction runs in parallel of the conventional IRS/PI3K/PKB-Akt pathway that leads to glucose uptake. This second pathway leads to glycogen synthase and/or pyruvate dehydrogenase activation, and so to the enhanced non-oxidative and/or oxidative glucose disposal. Recent data challenged this view since over a large collection of synthetic IPGs, none were found to be insulin mimetic (38). The existence and the physiological relevance of these IPGs remain therefore questionable. In order to challenge the hypothesis of a metabolic conversion of *myo*-inositol to *D-chiro*-inositol *in vivo*, we tested the effects of *myo*-inositol and *D-chiro*-inositol on Protein Kinase B activation state in mouse isolated gastrocnemius muscles, with or without insulin stimulation (**Fig. 3B**). According to our result however, *myo*-inositol but not *D-chiro*-inositol potentiated insulin induced PKB/Akt phosphorylation on Serine⁴⁷³. Hence *myo*-inositol effect on PKB/Akt activation *in vivo* (**Fig. 3A**) seems to be independent of its metabolic conversion to *D-chiro*-inositol.

Insulin sensitivity is strongly related to body fat content even within subjects with normal BMI (39). Since obesity has generally been regarded as an important contributory factor in peripheral insulin resistance, the question arises as to whether the lower adiposity of the *myo*-inositol mice is the primary factor responsible for the observed changes in insulin sensitivity noted in the present study (**Fig. 5**). Indeed, increased visceral fat is associated with decreases in peripheral and hepatic insulin sensitivity (40–42) and in good agreement, surgical extraction of visceral fat has been shown to reverse insulin resistance in young obese and old male rodents (43). We noticed in the present study a strong correlation between insulin sensitivity

(estimated through K_{ITT} index) and fat mass suggesting that fat mass loss could be a determining factor of *myo*-inositol insulin-sensitizing action in the long term, in addition to its action on insulin signalling in muscle. The exact mechanism involved in fat mass loss remains however to be defined. Adipose tissue is now recognized as a major secretory tissue (44) releasing into blood flow many hormones and cytokines (named adipokines) that affect metabolism. Several adipokines have been involved in insulin resistance (resistin, TNF- α , IL6,...) or as insulin sensitizing factor (adiponectin). However, *myo*-inositol treatment was not associated with an increase in plasma adiponectin level excluding a role for adiponectin in its insulin sensitizing effect. Hypertrophy of white adipose tissue exacerbates the secretion of pro-inflammatory cytokines, such as IL-6, IL-1, IL-8, TNF- α while regulatory cytokines, such as IL-10, are decreased. Accumulated fat is therefore associated with low-grade inflammation that could contribute to metabolic syndrome and insulin resistance associated with overweight (45,46). We noticed a significant decrease in plasma NEFA levels in *myo*-inositol mice (see **supplementary Fig. 4**). The adverse effects of increased NEFA availability on insulin sensitivity are well known from the works of Randle et al. (48) showing that increased availability of fatty acids decreases glucose utilization in muscle. NEFA are also a potent stimulus to hepatic glucose production (47), (48). The decrease of plasma NEFA level could therefore underlie the improvement of insulin sensitivity. Furukawa et al. (2004) reported that increased oxidative stress in accumulated fat was an important pathogenic mechanism of obesity-associated metabolic syndrome (49). Fat accumulation correlated with systemic oxidative stress in both humans and mice. Production of ROS was selectively increased in adipose tissue of obese mice, associated with a blunted expression of antioxidative enzymes. The decrease in WAT mass described in the present study could contribute to the better redox status of *myo*-inositol mice as evidenced by the measurement of plasma antioxidant activity. This effect can contribute to the improvement of insulin sensitivity as does most antioxidant substances (50–54). Of note, a recent study on Jian carp (55) confirmed the antioxidant potency of chronic *myo*-inositol treatment, showing that *myo*-inositol pre-supplementation prevented copper-induced oxidative damage *in vivo* and *ex vivo* on intestine, presumably through the induction of key antioxidant enzymes. Some studies also reported a direct antioxidant activity of phosphorylated forms of *myo*-inositol (i.e. phytic acid) via iron III chelation (56), and of derivatives such as *D-chiro*-inositol and D-pinitol, through the quenching of superoxide anion and hydroxyl radical (57).

As a conclusion, this study shows that a chronic treatment with *myo*-inositol 1) improves glucose tolerance in mouse by increasing insulin sensitivity 2) potentiates insulin action on the conventional PI3K/Akt insulin signalling pathway 3) reduces fat mass accretion 4) improves antioxidant status. Further studies are however required to decipher the mechanisms underlying those effects of *myo*-inositol. *Myo*-inositol only exhibited an extremely low toxicity as its oral LD50 in mouse is 10 000 mg.kg⁻¹ (*Myo*-inositol Material Safety Data Sheet). In Human, no serious adverse effects were observed in doses up to 18 g.day⁻¹ for up to 3 months. Only minor and non life threatening gastrointestinal adverse events were reported with daily intake of high doses of *myo*-inositol (up to 30 g.day⁻¹) (58). *Myo*-inositol could therefore constitute a viable and safe nutritional strategy to delay or prevent insulin-resistance development and/or type 2 diabetes onset.

Figures legends

Figure 1. Chronic treatment with *myo*-inositol ($1.2 \text{ mg}\cdot\text{g}^{-1}$ per day, ip) improved glucose tolerance and insulin sensitivity in mice. Glucose tolerance was explored using glucose tolerance test (GTT). **A** – Blood glucose level evolution after intraperitoneal administration of glucose ($1 \text{ g}\cdot\text{kg}^{-1}$ i.p) to fasting mice. **B**. Insulin plasma level at the hyperglycaemic phase (30 min after i.p. glucose injection) of the GTT. **C**. Plasma insulin concentration was measured after intraperitoneal administration of a non-glucose insulin secretagogue (Arginine, $1 \text{ g}\cdot\text{kg}^{-1}$). £, $P < 0.005$, difference from baseline level. Note that no difference was found to be significant between the 2 groups at $p < 0.05$ level **D**. Insulin sensitivity was explored using insulin tolerance test. Blood glucose level was measured after intraperitoneal injection of insulin ($0.3 \text{ UI}\cdot\text{kg}^{-1}$) to fasting mice. **Insert** – Plasmatic Glucose disappearance rate (K_{ITT}) during the insulin tolerance test. Results are expressed as mean $\pm$ SEM for $n=10$ mice in each group. * $p < 0.05$, ** $p < 0.01$, significant difference between saline and *myo*-inositol treated mice.

Figure 2. Insulin sensitivity is negatively correlated with central white adipose tissue mass. $n=20$. Central WAT was calculated as the sum of the intra-abdominal WAT pad weights, namely retroperitoneal and parametrial WAT pads.

Figure 3. *Myo*-inositol potentiated insulin signalling in skeletal muscle. **A**-Immunoblotting study of *in vivo* insulin induced phosphorylation of PKB/Akt in gastrocnemius muscle of mice daily treated with *myo*-inositol or saline. **B**- *Myo*-inositol for 15min potentiated insulin signalling in skeletal muscle *ex vivo*. Immunoblotting study of *ex vivo* insulin induced phosphorylation of PKB/Akt in gastrocnemius muscle. Mouse gastrocnemius muscle were incubated for 15 min with 1 mM *myo*-inositol, *D-chiro*-inositol or mannitol as a control and stimulated with insulin (100 nM, 15 min). Note that *myo*-inositol but not *D-chiro*-inositol potentiated insulin induced serine- phosphorylation of PKB/Akt. Results are expressed as mean $\pm$ SD for $n=3-5$ mice in each group. Different letters indicate a significant difference at the $p < 0.05$ level.

Figure 4. Chronic treatment with *myo*-inositol ($0.9 \text{ mg}\cdot\text{g}^{-1}$ per day, orally) reduces white adipose tissue accretion in mice. **A**- Respective weights of WAT depots for *myo*-inositol and control mice. Results are expressed as mean $\pm$ SEM for $n=14$ mice per group. ** $p < 0.01$

and *** $p < 0.005$. **B-** Total WAT mass relative to the body weight in *myo*-inositol and saline treated mice. **C,D-** Adipocytes volume frequency distribution. Individual measurements were performed on 12-14,000 adipocytes using osmium tetroxide - coulter counter procedure as described in Methods. Frequency distribution of adipocytes volumes for saline (dotted line) and *myo*-inositol (solid line) treated animals. Note that distribution of adipocyte volume was shifted leftward (ie. towards smaller volumes) in *myo*-inositol mice. In each group, adipocytes were pooled from 8-10 mice. **E-** lipolysis and **F-** lipogenesis measured on isolated adipocytes from saline *myo*-inositol treated mice (data are mean $\pm$ SEM for $n=5$). Abbreviations: ISO, isoproterenol ; WAT, white adipose tissue ; eWAT, epididymal WAT; rWAT, retroperitoneal WAT; scWAT, subcutaneous WAT.

Figure 5. Proposed mechanism of effects of chronic treatment with *myo*-inositol on insulin sensitivity in mice. Abbreviations: IPG, inositolphosphoglycans ; NEFA, non-esterified fatty acids ; PIPs, phosphorylated inositol-phospholipids (phosphoinositides) ; ROS, reactive oxygen species.

Table 1:
Biometric data and tissue weights in mice treated for 15 days with saline or *myo*-inositol (1.2mg.kg⁻¹ per day, ip)

	control	<i>myo</i> -inositol	change	p-value
Biometric data				
BW, g	31.7 ± 0.7	31.8 ± 1.0	0%	0.963
Body length, cm	10 ± 0.1	10.3 ± 0.1	+3%	0.362
Lee index	316 ± 3	308 ± 2	-3%	0.023*
Organ weights				
Liver, mg/10 g BW	394 ± 24	403 ± 14	+2%	0.749
Heart, mg/10 g BW	49 ± 2	46 ± 1	-6%	0.416

scWAT, mg/10g BW	95 ± 14	77 ± 7	-19%	0.269
Total WAT, mg/10g BW	391 ± 15	260 ± 37	-33%	0.009**

Data are mean ± SEM for n=14 in each group. Data were compared using Student t test and when appropriated Welch correction for variance inhomogeneity. Differences were considered significant at the p<0.05 level. Abbreviations: BW, body weight ; WAT, white adipose tissue ; pWAT, parametrial WAT ; rWAT, retroperitoneal WAT ; scWAT, subcutaneous WAT.

Table 2:
Plasma and tissue analysis in mice treated for 15 days with saline or *myo*-inositol (1.2mg.kg⁻¹ per day, ip)

	control	<i>myo</i> -inositol	change	p-value
Plasma glucose				
Fed glucose, mM	7.34 ± 0.26	6.61 ± 0.2	-10%	0.031*
Fasted glucose, mM	4.33 ± 0.28	4.61 ± 0.18	+6%	0.713
Fasted insulin, pM	257.7 ± 22.15	227.8 ± 23.2	-11%	0.996
HOMA-IR	1.70 ± 0.15	1.74 ± 0.19	+2%	0.895
Plasma adipokins				
Leptin, ng/ml	13.7 ± 3.1	5.1 ± 1.4	-63%	0.02*
Adiponectin, µg/ml	24.5 ± 1.0	25.9 ± 1.6	+6%	0.457
Plasma lipids				
Triacylglycerols, mM	1.31 ± 0.17	1.19 ± 0.15	-10%	0.349
NEFA, mM	0.54 ± 0.02	0.34 ± 0.01	-37%	<0.001***
Total cholesterol, mM	3.81 ± 0.34	3.26 ± 0.27	-16%	0.293
Plasma redox status				
Antioxidant activity, mM eq Uric acid	0.49 ± 0.03	0.72 ± 0.04	+46%	0.002***
Tissue lipid content				
Liver lipids, mg/g	47.8 ± 3.0	46.9 ± 3.5	-2%	0.852
Muscle lipids, mg/g	9.3 ± 2.4	9.0 ± 1.9	-3%	0.935

Data are mean ± SEM for n=10-12 in each group. Data were compared using Student t test and when appropriated Welch correction for variance inhomogeneity. Differences were considered significant at the p<0.05 level. Abbreviations: HOMA-IR, homeostasis model assessment of insulin-resistance ; NEFA, non esterified fatty acids.

Table 3:
Biometric data and organ weights in mice fed for 15 days with *myo*-inositol
(0.9mg.kg⁻¹ per day)

	control	<i>myo</i> -inositol	change	p-value
Biometric data				
BW, g	37.6 ± 1.2	34.9 ± 1.4	-7%	0.157
Body length, cm	10.6 ± 0.1	10.4 ± 0.2	-2%	0.279
Lee index	316 ± 3	314 ± 4	-1%	0.646
Organ weights				
Liver, mg/10g BW	422 ± 10	437 ± 13	+4%	0.413
Heart, mg/10g BW	45 ± 2	46 ± 1	+2%	0.496
Kidneys, mg/10g BW	114 ± 3	119 ± 5	+4%	0.373
Gastrocnemius, mg/10g BW	41 ± 2	44 ± 2	+7%	0.440
Tibialis, mg/10g BW	20 ± 1	20 ± 1	0%	0.992
Adipose tissue weights				
Total WAT, mg/10g BW	724 ± 70	447 ± 74	-38%	0.014*

Data are mean ± SEM for n=10 in each group. Data were compared using Student t test and when appropriated Welch correction for variance inhomogeneity. Differences were considered significant at the p<0.05 level. Abbreviations: BW, body weight, WAT white adipose tissue, pWAT, parametrial WAT, rWAT, retroperitoneal WAT, scWAT, subcutaneous WAT.

Table 4:
Cellularity of parametrial white adipose tissue in mice fed for 15 days with *myo*-inositol (0.9mg.kg⁻¹ per day)

	control	<i>myo</i> -inositol	change	p-value
pWAT, mg	830 ± 48	549 ± 81	-34%	0.015*
Cell diameter, µm	69.0 ± 2.0	59.8 ± 3.0	-13%	0.02*
Cell weight, ng	176.3 ± 15.6	117.8 ± 19.0	-33%	0.03*
Nb cells, x10 ⁶	5.21 ± 0.62	5.29 ± 1.23	+2%	0.950
DNA content µg/pad	63.0 ± 13.0	53.4 ± 10.1	-15%	0.568

Data are mean ± SEM for n=9-10 in each group. Data were compared using Student t test and when appropriated Welch's correction for variance inhomogeneity. Differences were considered significant at the p<0.05 level. Abbreviation: pWAT parametrial white adipose tissue.

Supplementary Figure 1

Supplementary Figure 1. Structures of the nine stereoisomers of inositol. Myo-inositol (framed) is the most common isomer of inositol in foodstuffs and animal tissues.

Supplementary Figure 2

Supplementary Figure 2. plasma leptin concentration is correlated to white adipose tissue (WAT) mass in control and *myo*-inositol treated mice (N= 19).

Supplementary Figure 3

Supplementary Figure 3. Typical pictures of osmium tetroxide-fixed adipocytes from saline (A,B) or *myo*-inositol treated mice (C,D). Adipocytes were isolated from epididymal fat pad as described in Methods. ($\times 100$). Note that adipocytes from *myo*-inositol mice were smaller than those from control mice.

Supplementary Figure 4

Supplementary Figure 4. Scattergram of plasma NEFA concentrations in control and *myo*-inositol-fed mice (N= 14-16). NEFA were assayed in the fasting state as described in Methods.
