## Abstract

**Introduction:** Nerve growth factor (NGF) level is increased in osteoarthritis (OA) joints and is involved in pain associated with OA. Stimuli responsible for NGF stimulation in chondrocytes are unknown. We investigated whether mechanical stress and proinflammatory cytokines may influence NGF synthesis by chondrocytes.

**Methods:** Primary cultures of human OA chondrocytes, newborn mouse articular chondrocytes or cartilage explants were stimulated by increasing amounts of IL-1 $\beta$ , prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), visfatin/nicotinamide phosphoribosyltransferase (NAMPT) or by cyclic mechanical compression (0.5 Hz, 1 MPa). Before stimulation, chondrocytes were pretreated with indomethacin, Apo866, a specific inhibitor of NAMPT enzymatic activity, or transfected by siRNA targeting visfatin/NAMPT. mRNA NGF levels were assessed by real-time quantitative PCR and NGF released into media was determined by ELISA.

**Results:** Unstimulated human and mouse articular chondrocytes expressed low levels of NGF (19.2  $\pm$  8.7 pg/mL, 13.5  $\pm$  1.0 pg/mL and 4.4  $\pm$  0.8 pg/mL/mg tissue for human and mouse articular chondrocytes and costal explants, respectively). Mechanical stress induced NGF release in conditioned media. When stimulated by IL-1 $\beta$  or visfatin/NAMPT, a proinflammatory adipokine produced by chondrocytes in response to IL-1 $\beta$ , a dose-dependent increase in NGF mRNA expression and NGF release in both human and mouse chondrocyte conditioned media was observed. Visfatin/NAMPT is also an intracellular enzyme acting as the rate-limiting enzyme of the generation of NAD. The expression of NGF induced by visfatin/NAMPT was inhibited by Apo866, whereas IL-1 $\beta$ -mediated NGF expression was not modified by siRNA targeting visfatin/NAMPT. Interestingly, PGE<sub>2</sub>, which is produced by chondrocytes in response to IL-1 $\beta$  and visfatin/NAMPT, did not stimulate NGF production. Consistently, indomethacin, a cyclooxygenase inhibitor, did not counteract IL-1 $\beta$ -induced NGF production.

**Conclusions:** These results show that mechanical stress, IL-1 $\beta$  and extracellular visfatin/NAMPT, all stimulated the expression and release of NGF by chondrocytes and thus suggest that the overexpression of visfatin/NAMPT and IL-1 $\beta$  in the OA joint and the increased mechanical loading of cartilage may mediate OA pain via the stimulation of NGF expression and release by chondrocytes.

## Introduction

Osteoarthritis (OA) is a chronic and age-related joint disease leading to cartilage destruction. Whereas the mechanisms by which this degradation happens are more and more understood, the reasons why an OA joint is painful are quite mysterious. For a same degree of cartilage degradation, some patients have symptoms and others have not. Recently, novel pharmacological molecules, belonging to the anti-nerve growth factor (NGF) family, have shown a dramatic effect on OA symptoms, much more efficacious than non-steroidal anti-inflammatory drugs (NSAIDs), the usual treatment for symptomatic OA [1-4]. Unfortunately, all clinical trials were halted in 2011 due to an unexpected increase in the number of total joint prosthesis in the active compared to the control groups [5]. Reviewing all the cases, it has been shown that this increase was due to an accelerated OA process in a few patients, especially those co-treated with NSAIDs. Nevertheless, NGF displays proinflammatory effects, including the stimulation of cytokine and prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) synthesis, monocyte differentiation, mast cell proliferation and degranulation [6]. Moreover, the injection of NGF into the synovium of rats increased the density of mast cells [7].

Since there is an unmet need for treating pain in OA patients, any explanations on the occurrence of such deleterious effects with anti-NGF drugs are welcome. It has been proposed that pain improvement allows increased joint activity leading to subsequent overuse [8]. More directly, NGF improves ligament healing [9] and decelerates chondrocyte differentiation *in vitro* [10], which is suspected to play an important role in OA progression. In addition, NGF can also display anti-inflammatory effects [11,12]. Notably, NGF inhibited interleukin (IL)-1 $\beta$ -induced tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) production in OA synovial fibroblasts [13].

Inflammatory factors, including IL-1 $\beta$ , TNF- $\alpha$  and adipokines [14] are found in increased levels in OA joints and are proposed to play a role in OA progression, especially by switching chondrocytes towards a catabolic phenotype. IL-1 $\beta$  downregulates the expression of cartilage extracellular matrix components, while it stimulates matrix metalloproteinase (MMP), cytokine and PGE<sub>2</sub> synthesis. Similarly, adipokines, including visfatin, stimulate the catabolic activity of chondrocytes [14,15]. NGF levels are increased in the synovial fluid of OA patients [16]. NGF and its two receptors, the high-affinity tyrosine kinase A receptor (trkA) and the low-affinity p75 receptor, are expressed by joint cells including chondrocytes [17,18] and are increased in OA cartilage [10,19]. Moreover, NGF synthesis is highly correlated with the degree of OA cartilage degradation in human [19].

Interestingly, NGF expression is induced in an inflammatory context and mediators such as IL-1 $\beta$  and PGE<sub>2</sub>

can stimulate NGF synthesis [13,20]. For example, intra-articular injection of IL-1 $\beta$  induces an increase in NGF levels [21]. However, stimuli responsible for NGF expression and production in OA cartilage remain to be determined. In the present study, we investigated whether mechanical stress and proinflammatory factors, two main determinants of OA, may influence NGF synthesis by chondrocytes. For this purpose, primary cultures of human OA chondrocytes and newborn mouse articular chondrocytes or cartilage explants were stimulated by increasing amounts of IL-1 $\beta$ , PGE<sub>2</sub>, visfatin or by cyclic mechanical compression. NGF mRNA expression and protein released into media were determined.

## Materials and methods

### Primary culture of human chondrocytes

Human cartilage samples were obtained from OA patients undergoing total knee arthroplasty at Saint-Antoine Hospital (Paris, France). Informed consent was obtained for each patient before surgery. The diagnosis of OA was based on clinical and radiographic evaluations according to the criteria of the American College of Rheumatology [22]. Experiments using human samples were approved by the local ethics committee (CPP Ile de France V, 2 May 2012).

Human articular chondrocytes were isolated by enzymatic digestion of cartilage, as previously described [15]. Cells were seeded in 12-well plates (500,000 cells/well) and allowed to grow to confluence in Dulbecco's modified Eagle's medium (DMEM) (4.5 mg/L glucose) supplemented with 10% fetal calf serum, 100 IU/mL penicillin, 100  $\mu$ g/mL streptomycin and 4 mM L-glutamine (Sigma-Aldrich, Saint Quentin Fallavier, France). Cells were then starved in serum-free medium containing 0.3% bovine serum albumin for 24 hours before stimulation.

### Primary culture of mouse chondrocytes

All experiments were performed according to the protocols approved by the French/European ethics committee. Immature murine articular chondrocytes were isolated by enzymatic digestion of articular cartilage from six-day-old newborn animals from one Swiss mouse litter (Janvier Labs, Le Genest Saint Isle, France), according to a previously described procedure [23]. Cells were seeded in 12-well plates (10,000 cells/cm<sup>2</sup>) and allowed to grow for six to seven days in DMEM (1 mg/L glucose) supplemented with 10% fetal calf serum, 100 IU/mL penicillin, 100  $\mu$ g/mL streptomycin and 4 mM L-glutamine (Sigma-Aldrich). Cells were then starved in serum-free medium containing 0.1% bovine serum albumin for 24 hours before stimulation.

### Cell stimulation

Human OA and murine articular chondrocytes were stimulated with IL-1 $\beta$  (PeproTech, from Tebu Bio, Le Perray-en-Yvelines, France; 0.1 to 10 ng/mL from 2 to

24 hours), PGE<sub>2</sub> (Cayman Chemical, from SPI-Bio, Montigny-le-Bretonneux, France; 0.1 to 10 µM for 24 hours), or visfatin (Alexis Biochemical, Paris, France; 1 to 10 µg/mL for 24 hours) dissolved in starvation media. In additional experiments, chondrocytes were co-incubated with either IL-1β (1 ng/mL) and indomethacin (Sigma-Aldrich; 0.1 to 10 µM), an inhibitor of the cyclooxygenase activity, or IL-1β (1 ng/mL) and visfatin (5 µg/mL) or visfatin (5 µg/mL) and Apo866 (10 nM) (generously provided by Alexander So; Astellas Pharma, Munich, Germany), an inhibitor of the nicotinamide phosphoribosyltransferase activity of visfatin.

After stimulation, cells were disrupted in lysis buffer (RLT, from Qiagen, Courtaboeuf, France) and conditioned media were stored at -80°C until analysis.

#### Transfection of small interfering RNA (siRNA)

Small interfering RNA (siRNA) directed against mouse visfatin was designed and purchased from Ambion Cenix (Austin, TX, USA). The sequence specific for mouse visfatin was forward 5'-GGCACCACUAAUCAUCAGAtt-3', reverse 5'-UCUGAUGAUUAGUGGUGCCtc-3'.

Mouse chondrocytes were cultured as described above. Confluent cells were removed with trypsin, and 6 × 10<sup>5</sup> chondrocytes were seeded in 6-cm tissue culture plates and grown for 24 hours, to 70 to 80% confluence. Normal growth medium containing 10% fetal bovine serum was changed prior to siRNA transfection. Transfections were performed as described for the RNAi Starter Kit (Qiagen). Cells were incubated for 18 hours with siRNA and transfection reagent, rinsed twice with phosphate-buffered saline (PBS), and placed in DMEM (1 mg/L glucose) supplemented with penicillin, streptomycin, and L-glutamine containing 1% BSA, with or without IL-1β (10 ng/ml) for 24 hours. Transfection of siRNA against MAPK-1, a ubiquitously produced mouse cell protein, was used as a positive control. A nonsilencing siRNA that has no homology with any known mammalian gene (RNAi Starter Kit) and scrambled siRNA (Ambion) were used as negative controls.

#### Mechanical compression

Mechanical compression was applied on costal cartilage, as previously described [24]. Briefly, ribs cages from six-day-old newborns from one Swiss mouse litter (Janvier Labs) were harvested and cartilage was separated from bone and soft tissues. Immediately after dissection, each sample, consisting of 50 mg of cartilage explants, were placed into Biopress culture plates (Flexercell International, Hillsborough, NC, USA) in DMEM (1 mg/L glucose) supplemented with 30 mM Hepes, 100 IU/mL penicillin, 100 µg/mL streptomycin and 4 mM L-glutamine (Sigma-Aldrich). During 4 to 24 hours, intermittent compression was applied by the Biopress system (Flexercell International) using a

sinusoidal waveform at 0.5 Hz and 1.0 MPa of magnitude (Figure S1 in Additional file 1). Control explants were kept in unloaded condition.

After compression, cartilage explants frizzed in liquid nitrogen and conditioned media were stored at -80°C until analysis.

#### RNA extraction, reverse transcription and quantitative real-time PCR

Total RNA was extracted from cultured cells with RNeasy Mini kit (Qiagen) according to the manufacturer's instructions. Total RNA was reverse transcribed with Omniscript RT kit according to the manufacturer's instructions (Qiagen). NGF mRNA expression was analyzed by quantitative real-time PCR using the Light Cycler 480 (Roche Diagnostics, Meylan, France). The equivalent of 5 to 10 ng initial RNA was subjected to PCR amplification in a 12 µl final volume using specific primers at 10 µM and LC 480 SYBR Green I Master kit (Roche Diagnostics). PCR amplification conditions were: initial denaturation for 5 min at 95°C followed by 40 cycles consisting of 10 s at 95°C, 15 s at 60°C and 10 s at 72°C. Product formation was detected at 72°C in the fluorescein isothiocyanate channel. The generation of specific PCR products was confirmed by melting curve analysis. For each PCR, cDNAs were run in duplicate in parallel with serial dilutions of a cDNA mixture tested for each primer pair to generate a standard linear curve, which was used to estimate the amplification efficiency for NGF and HPRT. The relative mRNA expression of NGF normalized to that of HPRT, used as internal reference gene, was determined by the Efficiency method of the LightCycler 480 Software.

The specific oligonucleotide primers used were as follows: human NGF, sense 5'GTCATCATCCCATCCCATCT<sup>3'</sup> and anti-sense 5'AGTACTGTTTGAATACACTGTGT<sup>3'</sup>TAAT<sup>3'</sup>; mouse NGF, sense 5'CACCCACCCAGTCTTCC<sup>3'</sup> and anti-sense 5'CTCGGCACCTTGGTCTCAAA<sup>3'</sup>; human GAPDH, sense 5'CCATCACCATCTTCCA<sup>3'</sup> and anti-sense 5'CCTTCTCCATGGTGGT<sup>3'</sup>; mouse HPRT, sense, 5'GCTGGTGAAAAGGACCTCT<sup>3'</sup> and anti-sense, 5'CACAGGACTAGAACACCTGC<sup>3'</sup>.

#### NGF assay

NGF concentrations in the medium were measured using an enzyme-linked immunosorbent assay (ELISA) kit from Promega (Charbonnières, France) according to the manufacturer's instructions. The detection limit of NGF was 7.8 pg/mL and the intra-assay coefficients of variance was 4.2%. The NGF concentrations were analyzed in duplicate at serial dilution and were read against a standard curve.

#### Statistical analysis

Results are expressed as means ± standard deviation (SD). Results were compared using one-way factorial

analysis (analysis of variance) followed by the Scheffé's *F* test (Statview software, version 4.57; Abacus Concepts Inc., Berkeley, CA, USA). Statistical significance was accepted for  $P < 0.05$ .

## Results

### Induction of NGF expression and release by costal cartilage explants in response to mechanical stress

Since mechanical overload is considered as a strong inducer of cartilage damage and pain, the influence of *in vitro* mechanical compression on NGF release by costal cartilage explants was investigated. For this purpose, murine costal cartilages were subjected to intermittent compression for 4 and 24 hours. Costal cartilage explants constitutively released low levels of NGF that accumulated within conditioned media between 4 and 24 hours (Figure 1A). Compression for 4 hours did not stimulate NGF release. In contrast, accumulation of NGF into tissue-conditioned media was significantly increased after compression for 24 hours (4.7-fold increase versus control,  $P = 0.04$ ) (Figure 1).

### Induction of NGF expression and release by articular chondrocytes in response to visfatin

Visfatin is an adipokine found in OA synovial fluids [25], which displays catabolic activity on chondrocytes [15]. We thus determined whether NGF expression and release could be modulated by visfatin. Human OA and mouse articular chondrocytes were stimulated with increasing concentrations of visfatin (1, 2.5, 5 and 10  $\mu\text{g/mL}$ ) for 24 hours and NGF mRNA expression and release into conditioned media was measured. Both human and mouse articular chondrocytes spontaneously synthesized NGF

mRNA and protein (Figure 2). Visfatin induced a dose-dependent increase in NGF mRNA expression in human OA chondrocytes (Figure 2A). The stimulation of NGF mRNA expression was observed with 1  $\mu\text{g/mL}$  visfatin and became statistically significant with 2.5  $\mu\text{g/mL}$  visfatin (14-fold increase as compared to control,  $P = 0.02$ ). Consequently, an accumulation of NGF into human chondrocyte-conditioned media was measured after visfatin stimulation (Figure 2B). Similarly, a dose-dependent increased accumulation of NGF was observed in conditioned media of mouse articular chondrocytes (Figure 2C). A significant increase, as compared to unstimulated chondrocytes, was obtained with 2.5  $\mu\text{g/mL}$  visfatin (2.6-fold versus control,  $P = 0.03$ ) and the highest concentration of visfatin (10  $\mu\text{g/mL}$ ) induced the highest accumulation of NGF into cell supernatant (4.9-fold versus control,  $P = 0.0003$ ) (Figure 2C). Visfatin-mediated release of NGF was associated with an increase in NGF mRNA expression (2-fold versus control,  $P = 0.045$ ) (Figure 2C, inset).

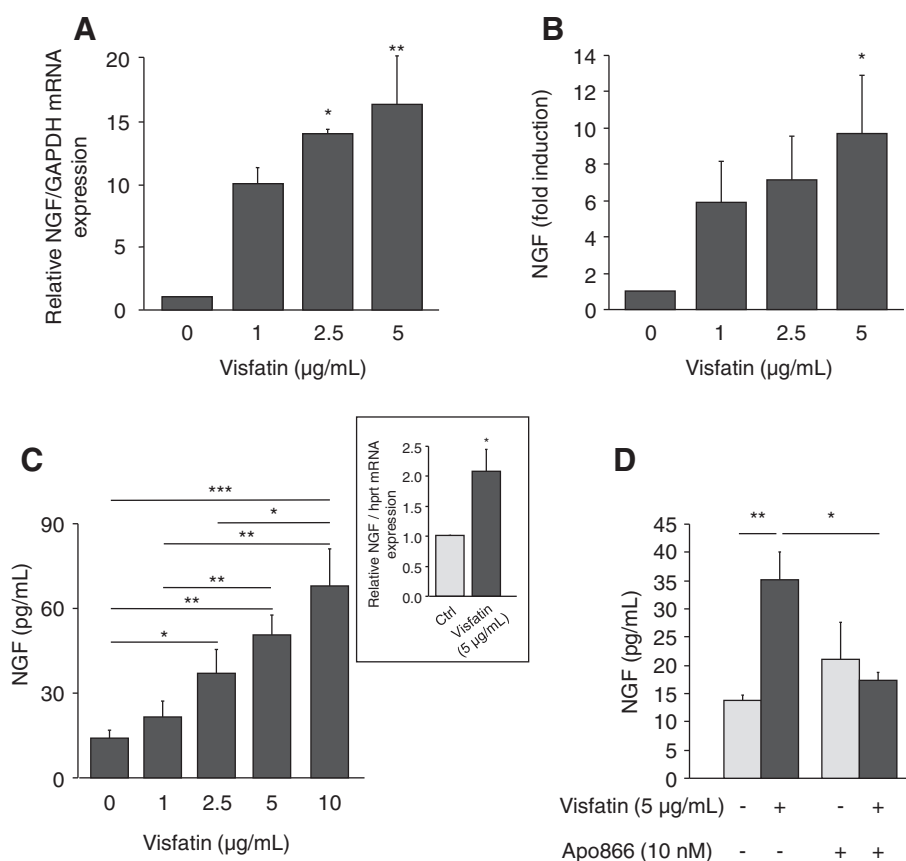

In addition to its cytokine-like activity, visfatin displays a nicotinamide phosphoribosyltransferase (NAMPT) enzymatic activity responsible for the synthesis of nicotinamide adenine dinucleotide (NAD). Several lines of evidence support the involvement of this enzymatic activity in the cellular effects of visfatin/NAMPT [26]. To investigate the involvement of visfatin/NAMPT enzymatic activity in NGF stimulation, chondrocytes were pretreated with 10 nM Apo866, a specific inhibitor of NAMPT [27], for 4 hours before the addition of exogenous visfatin/NAMPT (5  $\mu\text{g/mL}$ ). Apo866 treatment led to a 56% and 68% drop in NAD concentration in control and visfatin/NAMPT-treated chondrocytes ( $P = 0.0003$  and  $P < 0.0001$ , respectively) (not shown). The inhibition of visfatin/NAMPT enzymatic activity by Apo866 prevented the increase in NGF synthesis ( $P = 0.02$  versus visfatin/NAMPT-treated cells without Apo866) (Figure 2D). In contrast, no modification of spontaneous release of NGF by chondrocytes was observed in the presence of Apo866.

### Induction of NGF expression and release by articular chondrocytes in response to IL-1 $\beta$

We next investigated the action of IL-1 $\beta$  on NGF mRNA expression and release by human OA and murine articular chondrocytes. IL-1 $\beta$  dose-dependently increased NGF mRNA expression in human OA articular chondrocytes (Figure 3A). A 9.3-fold induction was observed with 0.1 ng/mL IL-1 $\beta$  and became statistically significant with 1 ng/mL ( $P = 0.004$ ). This was associated with increased levels of NGF measured in conditioned media of chondrocytes stimulated with IL-1 $\beta$  (Figure 3B). IL-1 $\beta$  also stimulated NGF mRNA expression in mouse articular chondrocytes since a 1.8-fold induction was observed with 0.1 ng/mL IL-1 $\beta$  and became statistically significant with 1 ng/mL ( $P = 0.01$ ). NGF mRNA expression further

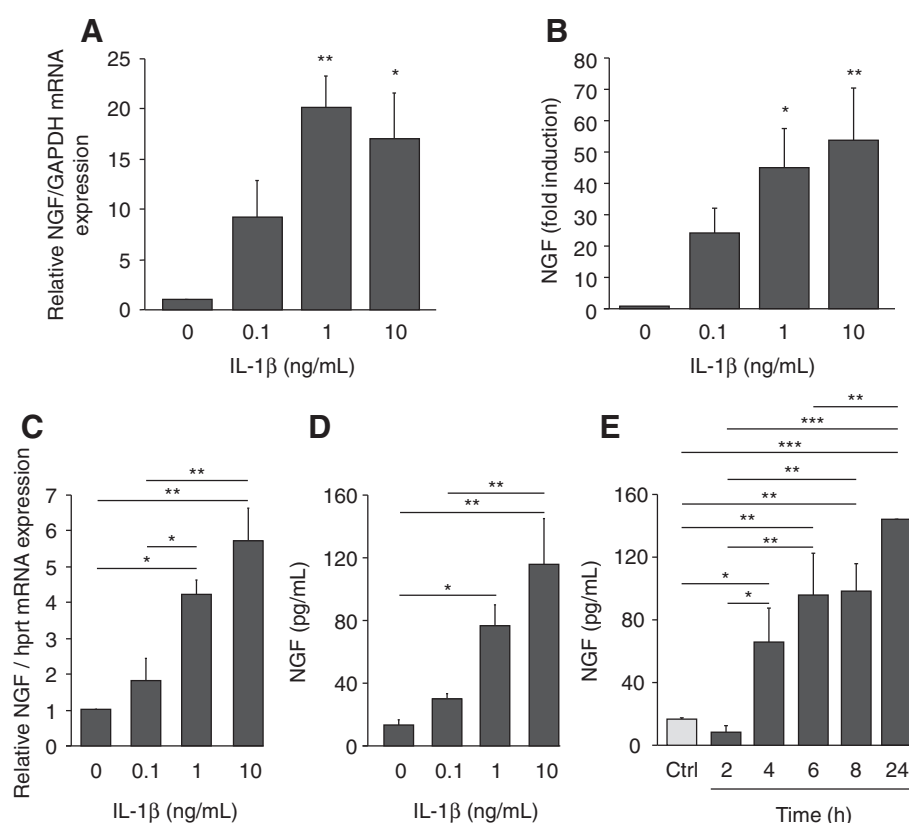

**Figure 2 Visfatin induces NGF expression and release by chondrocytes.** Human OA chondrocytes were stimulated for 24 hours with increasing concentrations of visfatin (0, 1, 2.5 and 5 µg/mL) and NGF mRNA expression (**A**) and release into cell supernatant (**B**) were measured by quantitative RT-PCR and ELISA, respectively (n = 3). Control cells released  $20.4 \pm 12.2$  pg/mL NGF. (**C**) Primary cultures of mouse articular chondrocytes were stimulated for 24 hours with increasing concentration of visfatin (0, 1, 2.5, 5 and 10 µg/mL) and NGF levels were measured in conditioned media (n = 3). Inset: NGF mRNA expression was determined by quantitative RT-PCR in control cells and chondrocytes stimulated with visfatin (5 µg/mL) for 24 hours. The amount of NGF mRNA was normalized against the amount of HPRT mRNA measured in the same cDNA. (**D**) Mouse articular chondrocytes were incubated with or without Apo866 (10 nM) for 4 hours and then treated or not with visfatin (5 µg/mL) for 24 hours (n = 3). NGF release was determined into cell-conditioned media. \* $P < 0.05$ , \*\* $P < 0.01$ , \*\*\* $P < 0.001$ . ELISA, enzyme-linked immunosorbent assay; NGF, nerve growth factor; OA, osteoarthritis.

increased using 10 ng/mL of IL-1 $\beta$  (5.7-fold compared to control,  $P = 0.004$ ). IL-1 $\beta$ -induced NGF mRNA expression paralleled the release of NGF protein into cell-conditioned media (Figure 3C and D). NGF protein release was slightly increased at 0.1 ng/mL and this increase became significant at 1 ng/mL IL-1 $\beta$  ( $P = 0.024$ ). In the time-course experiment, IL-1 $\beta$ -induced NGF release was observed after a 4-hour stimulation (4.2-fold increase versus control,  $P = 0.049$ ) and further increased up to 24 hours (9.2-fold increase versus control,  $P = 0.0005$ ) (Figure 3E).

IL-1 $\beta$  is a strong inducer of PGE<sub>2</sub> synthesis by cartilage and chondrocytes. However, PGE<sub>2</sub> was not involved in IL-1 $\beta$ -mediated NGF stimulation. Indeed, PGE<sub>2</sub> (0.01 to 10 µM) did not stimulate NGF release by articular chondrocytes (Figure 4A). Furthermore, indomethacin (0.1 to

10 µM), a specific inhibitor of cyclooxygenase enzymatic activity, was unable to prevent the release of NGF induced by IL-1 $\beta$  (1 ng/mL) (Figure 4B), although it efficiently inhibited the IL-1 $\beta$ -mediated production of PGE<sub>2</sub> by chondrocytes (not shown).

Since some of the effects of IL-1 $\beta$  on chondrocytes involve visfatin/NAMPT [15], consequences of visfatin/NAMPT knockdown on IL-1 $\beta$ -mediated NGF stimulation were assessed (Figure 4C). No effect of visfatin/NAMPT siRNA on the constitutive release of NGF was observed. Similarly, the potent stimulation of NGF secretion induced by IL-1 $\beta$  (10 ng/mL) (5-fold as compared to control,  $P > 0.0002$ ) was not blocked by visfatin/NAMPT siRNA, suggesting that endogenous visfatin/NAMPT is not involved in the IL-1 $\beta$ -stimulated release of NGF by chondrocytes (Figure 4C).

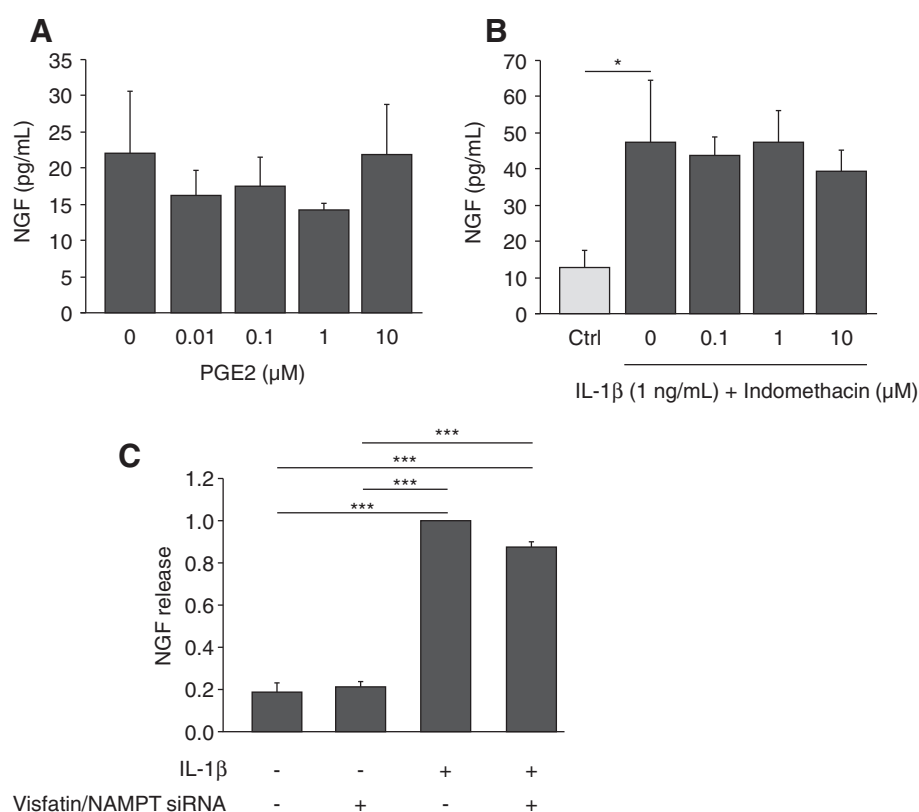

**Figure 3 Stimulation of articular chondrocyte expression and release of NGF by IL-1β.** Human OA chondrocytes were stimulated for 24 hours with increasing concentrations of IL-1β (0, 0.1, 1 and 10 ng/mL) and NGF mRNA expression (**A**) and release into cell supernatant (**B**) were measured by quantitative RT-PCR and ELISA, respectively (n = 4). Control cells released  $19.2 \pm 8.7$  pg/mL NGF. (**C-E**) Primary cultures of mouse articular chondrocytes were stimulated either with increasing concentrations of IL-1β (0, 0.1, 1 and 10 ng/mL) for 24 hours (n = 3) (**C and D**) or with IL-1β (10 ng/mL) for 2, 4, 6, 8 and 24 hours (n = 3) (**E**). As a control (ctrl), chondrocytes were incubated without IL-1β for 24 hours (**E**). NGF mRNA expression was determined by quantitative RT-PCR (**C**). The amount of NGF mRNA was normalized against the amount of HPRT mRNA measured in the same cDNA. NGF protein levels were measured in conditioned media by ELISA (**D and E**). \* $P < 0.05$ , \*\* $P < 0.01$ , \*\*\* $P < 0.001$ . ELISA, enzyme-linked immunosorbent assay; IL-1β, interleukin 1β; NGF, nerve growth factor; OA, osteoarthritis.

### Potential of IL-1β-stimulated NGF expression and release by visfatin/NAMPT

To determine whether the stimulation of NGF mRNA expression and release by IL-1β and visfatin/NAMPT could be additive, murine articular chondrocytes were co-stimulated with IL-1β (1 ng/mL) and visfatin/NAMPT (5 μg/mL). A slight potentiation of IL-1β-mediated stimulation of NGF was observed both at mRNA (1.4-fold) and protein levels (1.3-fold) when chondrocytes were co-stimulated with visfatin/NAMPT (Figure 5). This potentiation was similar to the stimulatory effect of visfatin/NAMPT since visfatin/NAMPT induced a 1.5-fold and 1.4-fold stimulation of NGF mRNA expression and release, respectively (Figure 5). Compression did not further increase the release of NGF from cartilage induced by either IL-1β or visfatin/NAMPT or IL-1β and visfatin/NAMPT (not shown).

### Discussion

Several lines of evidence highlight NGF as an attractive therapeutic target to control OA pain. NGF is a key factor in inflammation-associated hyperalgesia, whose protein is detected in OA synovial fluid [16] and mRNA expression is enhanced in OA chondrocytes [19]. NGF may also mediate joint damage [6]. Preclinical studies on experimental models of joint pain [1,3] and clinical trials on OA patients [2,4] thus evidenced the efficiency of NGF targeting in the reduction of joint pain. However, the increased number of total joint prosthesis due to acceleration in lesion progression in some patients decided the FDA to stop all clinical trials. A better understanding of the involvement of NGF in OA is therefore required. In this study, we investigated whether proinflammatory factors and mechanical compression, the main determinants of OA, may lead to the expression and the release of NGF by chondrocytes.

**Figure 4** PGE<sub>2</sub> and endogenous visafatin/NAMPT are not involved in IL-1β-mediated stimulation of NGF release by articular chondrocytes.

(A and B) Primary cultures of mouse articular chondrocytes were stimulated for 24 hours either with increasing concentrations of PGE<sub>2</sub> (0, 0.01, 0.01, 1 and 10 ng/mL) (n = 3) (A) or with IL-1β (1 ng/mL) in the presence of increasing concentrations of indomethacin (0, 0.1, 1, 10 μM) (n = 3) (B). As a control (ctrl), chondrocytes were incubated without IL-1β for 24 hours (B). NGF protein levels were measured in conditioned media by ELISA. (C) Primary culture of mouse articular chondrocytes were transfected by siRNA targeting visfatin/NAMPT before stimulation with IL-1β (10 ng/mL) for 24 hours (n = 2). Each experiment was performed in triplicate. Results are expressed as NGF release as compared to IL-1β-stimulated chondrocytes. \*P < 0.05, \*\*\*P < 0.001. ELISA, enzyme-linked immunosorbent assay; IL-1β, interleukin 1β; NAMPT, nicotinamide phosphoribosyltransferase activity. **Figure 5** Potentiation of IL-1β-stimulated NGF expression and release by visfatin/NAMPT. Primary cultures of mouse articular chondrocytes were stimulated or not for 24 hours either with IL-1β (1 ng/mL) or visfatin/NAMPT (5 μg/mL) or with IL-1β (1 ng/mL) and visfatin/NAMPT (5 μg/mL) (n = 3). The mRNA expression of NGF (A) and the NGF protein levels in chondrocyte conditioned media were determined (B). \*P < 0.05, \*\*\*P < 0.001. IL-1β, interleukin 1β; NAMPT, nicotinamide phosphoribosyltransferase activity. Suppress activity; NGF, nerve growth factor.

We first show that human OA chondrocytes as well as mouse cartilage and articular chondrocytes constitutively expressed NGF mRNA and released NGF protein into conditioned media, as already reported by Iannone *et al.* [19] in human normal articular chondrocytes. We also observed an increase in NGF expression and release in response to OA stimuli, consistently with the enhanced expression of NGF by OA chondrocytes [19]. In this context, we show for the first time that dynamic compression induced the release of NGF by cartilage, highlighting NGF as a mechanosensitive gene in chondrocytes. This result is in accordance with data showing that mechanical stretch can modulate NGF expression with an induction observed in smooth muscle cells [28] and sympathetic neurocytes [29], whereas a downregulation was obtained in rat cardiomyocytes [30].

We also show that IL-1 $\beta$ , which is considered as the main inflammatory mediator involved in cartilage degradation in OA, induced in a time- and dose-dependent manner an increase in NGF expression and release by both human and mouse articular chondrocytes. Similarly, IL-1 $\beta$  has been reported to stimulate the expression of NGF in several cell types, including human nucleus pulposus cells isolated from patients with intervertebral disc (IVD) degeneration [31-33]. The intra-articular injection of IL-1 $\beta$  induced an increase in NGF levels [21] and a positive correlation between IL-1 $\beta$  and NGF immunostaining in human IVD tissues was observed [34].

In addition to its well-known pro-degradative property on cartilage, IL-1 $\beta$  plays also a role in joint pain. Indeed, IL-1 $\beta$  levels in OA synovial fluids are associated with pain and hyperalgesia of the temporomandibular joint [35] and the synovial mRNA expression of IL-1 $\beta$  is correlated with the degree of pain in rotator cuff diseases [36]. OA patients showing a 2-fold higher expression of IL-1 $\beta$  by peripheral blood leukocytes compared to non-OA controls have higher pain scores and risks of radiographic OA progression than patients displaying similar peripheral blood leukocyte IL-1 $\beta$  expression than non-OA controls [37]. Furthermore, a reduced pain was obtained following the treatment of patients with chronic active gouty arthritis with rilonacept, an inhibitor of IL-1 $\beta$  [38]. Similarly, the subcutaneous injection of canakinumab, an anti-human IL-1 $\beta$  antibody, to patients with cryopyrin-associated periodic syndrome provoked a sustained remission of symptoms, including pain [39]. All these data suggest that IL-1 $\beta$ -mediated stimulation of NGF expression by chondrocytes may account for the pain associated with IL-1 $\beta$  levels in OA joints.

Adipokines have recently been proposed as molecular mediators probably involved in OA [40]. Among them, visfatin/NAMPT was characterized as a visceral fat

cytokine, a 52 kDa protein with insulin mimetic activity [41]. Visfatin/NAMPT is released by all joint tissues in OA patients [25] and its concentration in synovial fluids is linked to cartilage degradation biomarkers [42]. Visfatin/NAMPT stimulates chondrocyte catabolic activity measured by PGE<sub>2</sub> and protease synthesis [15] and induces the expression of several proinflammatory cytokines by chondrocytes (Laiguillon, submitted). Our results show that visfatin also stimulated both NGF expression and release by human OA and mouse articular chondrocytes, suggesting that it may favor OA pain in addition to mediate cartilage damage.

In addition to its cytokine-like activity, visfatin displays a NAMPT enzymatic activity responsible for the synthesis of NAD. NAD biosynthetic activity of visfatin/NAMPT is involved in some cellular effects of extracellular visfatin/NAMPT [43-45]. Interestingly, the pharmacological inhibition of visfatin/NAMPT by Apo866, a specific inhibitor of NAMPT activity, prevents arthritis progression [46,47]. In a previous study, we showed that blocking NAMPT enzymatic activity inhibited the catabolic response of chondrocytes to exogenous visfatin/NAMPT [26]. Similarly, we show here that NAMPT enzymatic activity was also crucial for the visfatin/NAMPT-mediated NGF stimulation in chondrocytes, suggesting the involvement of NAD in the signaling pathway of visfatin/NAMPT leading to NGF expression. NAD-consuming proteins, including sirtuins and poly(ADP-ribose) polymerases (PARPs), are known actors in the expression of many genes [48]. However, nothing is known about a putative role of such proteins in the expression of NGF. In addition, NAD consumption generates second messengers, which contribute to intracellular calcium signaling [49]. Intracellular calcium can regulate the expression of NGF [28,30].

IL-1 $\beta$ -mediated NGF expression involves nuclear factor kappa B (NF- $\kappa$ B) activity [50]. Interestingly, the proinflammatory effect of visfatin/NAMPT requires NF- $\kappa$ B activity in a NAMPT enzymatic activity-dependent manner. Some of the effects of IL-1 $\beta$  involve endogenous visfatin/NAMPT, as demonstrated by siRNA strategy [15]. However, we did not obtain any inhibition of IL-1 $\beta$ -mediated NGF secretion by using siRNA targeting endogenous visfatin/NAMPT, showing that endogenous visfatin/NAMPT is not involved in the stimulation of NGF induced by IL-1 $\beta$ . As NAD-derived second messengers activate intracellular calcium signaling, these results could explain why intracellular calcium signaling is not involved in IL-1 $\beta$ -mediated NGF expression [51]. Taken together, our results support that different signaling pathways, requiring endogenous visfatin/NAMPT or not, can be activated by IL-1 $\beta$ . Our results also show that the stimulation of NGF

expression and release in response to IL-1 $\beta$  and visfatin/NAMPT involves different pathways, thus explaining the potentiation of IL-1 $\beta$ -mediated stimulation of NGF expression and release by visfatin/NAMPT.

Interestingly, mechanical loading, IL-1 $\beta$  and visfatin all induce PGE<sub>2</sub> production by cartilage and chondrocytes [15,52,53]. PGE<sub>2</sub> was reported to induce the expression of NGF in mouse astrocyte cultures [54,55]. Blocking the generation of prostaglandins by celecoxib (Celebrex) prevented the increased secretion of NGF by tooth perfusates in rats after an inflammatory stress [56]. PGE<sub>2</sub> may be also involved in IL-1 $\beta$ -mediated pain [57]. PGE<sub>2</sub> may thus represent a common way for NGF expression in chondrocytes in response to OA stimuli. However, our results show that PGE<sub>2</sub>, whatever the concentration used, was unable to induce NGF expression and release in chondrocytes. In addition, indomethacin, an inhibitor of cyclooxygenase enzymatic activity, did not prevent the IL-1 $\beta$ -mediated increase in NGF expression in chondrocytes. These results suggest that the increased chondrocyte expression of NGF in response to several OA stimuli did not involve PGE<sub>2</sub>. In contrast, other studies showed that PGE<sub>2</sub> modulates the expression and synthesis of NGF. Friedman *et al.* reported that indomethacin partly blocked the increase in NGF production in response to IL-1 $\beta$  in embryonic rat hippocampal cultures [20]. PGE<sub>2</sub> stimulates the secretion of NGF in astrocytes [54,55], whereas in 3T3-L1 adipocytes it decreases both NGF expression and synthesis [58]. Thus, the influence of PGE<sub>2</sub> on NGF synthesis appears to be cell-type-dependent and may be related to the differential expression pattern of PGE<sub>2</sub> receptor in these cells. High amounts of E-type prostanoid (EP)3 receptor are indeed expressed in mature adipocytes [59], whereas chondrocytes express low levels of EP3 [60,61].

## Conclusions

OA is a painful disease, in which NGF plays a crucial role. Indeed, pivotal clinical trials have demonstrated that counteracting NGF leads to a dramatic reduction of OA pain [2]. Unfortunately, all the NGF antibodies in development have induced an acceleration of the OA process in a subgroup of patients. It is thus mandatory to accumulate more information on the mechanism of action of NGF in order to enhance the benefit-risk ratio of this new family of effective symptomatic drugs. Our results show that two main OA determinants, mechanical stress and proinflammatory factors, including IL-1 $\beta$  and extracellular visfatin/NAMPT, stimulated the expression and the release of NGF by articular chondrocytes. These results suggest that OA pain may involve the release of NGF by chondrocytes in response to the increased levels of IL-1 $\beta$  and extracellular visfatin/NAMPT, and to the increased mechanical loading of cartilage.
