Abstract:	Carbapenemase-producing Enterobacteriaceae (CPE) have emerged as a major source of bacterial resistance and their dissemination is a serious public health threat. ¹ It has also been demonstrated that those bacteria could disseminate outside the hospital setting. A large study including 34 hospitals in Spain demonstrated that a significant proportion of patients identified as colonized or infected with CPE during hospitalization probably acquired this multi-resistant organism in a nursing home during the period preceding their hospital admission. ² In addition, a recent review of the literature demonstrated that according to US-based studies, the percentage of CPE isolates that could be associated with the community ranged from 5.6 to 10.8%. ³

1 To the Editor - Carbapenemase-producing Enterobacteriaceae (CPE) have emerged
2 as a major source of bacterial resistance and their dissemination is a serious public
3 health threat.¹ It has also been demonstrated that those bacteria could disseminate
4 outside the hospital setting. A large study including 34 hospitals in Spain
5 demonstrated that a significant proportion of patients identified as colonized or
6 infected with CPE during hospitalization probably acquired this organism in a nursing
7 home during the period preceding their hospital admission.² In addition, a recent
8 review of the literature demonstrated that according to US-based studies, the
9 percentage of CPE isolates that could be associated with the community ranged from
10 5.6 to 10.8%.³

11 We have recently demonstrated the less effective effect of fecal microbiota
12 transplantation (FMT) on CPE as compared to vancomycin-resistant Enterococci
13 (VRE) fecal carriage.⁴ Those results are consistent with another recent study⁵
14 conducted in six patients colonized with CPE and showing an eradication of the
15 colonization in only 2/6 patients. In these studies, the decolonization procedure
16 included only one FMT. One hypothesis is that a protocol including iterative FMT
17 separated each other by a several-day latency could increase the effectiveness of
18 the procedure.

19 Our objective was to evaluate the impact of iterative MFT for the clearance of CPE
20 carriage in our mouse model of digestive colonization.

21 Ethical approval was obtained from the Ethical Committee in Animal Experimentation
22 of Pays-de-la-Loire, France (reference: 2015041415088410/APAFIS 513) and
23 conducted according to European directives concerning the use of animals in
24 research (86/609/EEC).

1
2 Twenty-eight 8-week old mice (Swiss type) were used for the model. The normal
3
4 digestive flora was disrupted with the daily oral administration of a combination of
5
6 antimicrobial agents including vancomycin (50 mg/kg), metronidazole (25 mg.kg) and
7
8 ceftriaxone (25 mg.kg) during 5 days (from day 1 to day 5). Mice were then
9
10 randomized to receive a high inoculum ($5 \cdot 10^9$ bacteria) of a strain of *Escherichia coli*
11
12 producing a New Delhi metallo- β -lactamase -1 (NDM-1). Those bacteria were
13
14 inoculated to the mice by oral gavage on day 4, day 5, and day 8. Mice were housed
15
16 in individual cages.
17
18
19

20
21 FMT was collected daily from related (Swiss mice of the same age) untreated mice.
22
23 Stool suspensions for FMT were prepared and stored as previously described.⁴ On
24
25 day 10, mice were randomized to receive FMT (14 mice) or placebo (14 mice).
26
27 During the experiment, 4 series of FMT or placebo administration were administered
28
29 to the mice. In each series, the mice received FMT or placebo once daily for three
30
31 successive days (from day 10 to day 12, from day 23 to day 25, from day 37 to day
32
33 39, and from day 49 to day 51) by oral gavage with 200 μ L of the stool suspension or
34
35 200 μ L of saline.
36
37
38
39
40

41 Stools were collected 3 times a week until day 57 and were weighted for quantitative
42
43 cultures. They were seeded on agar media (ChromID CARBA, bioMérieux, France)
44
45 after serial dilutions for CPE screening. Bacterial identification of CPE colonies was
46
47 controlled by using the MALDI-TOF technology (Vitek MS, bioMérieux). A mouse was
48
49 considered decolonized when 3 successive stool samples (corresponding to 4 or 5
50
51 days of follow-up) were found negative for CPE.
52
53
54

55 The evolution of the percentage of colonized mice during the follow-up period was
56
57 studied by the Kaplan-Meier analysis (SPSS software v15.0). The comparison
58
59
60
61
62
63
64
65

1 between the FMT group and the placebo group was performed by using the log-rank
2 test. The comparison of the percentage of colonized mice in each group at day 57
3
4 was performed with the Fisher exact test. A p value < 0.05 was considered
5
6 statistically significant.
7
8
9

10
11 The results are presented on figure 1. Overall, by considering the placebo effect
12 corresponding to the natural clearance of CPE digestive colonization of mice, the
13 iterative FMT series demonstrated a moderate impact on the decolonization kinetics
14 ($p = 0.22$). However, by considering the difference between the FMT protocol and the
15 placebo at the end of the follow-up period, the decolonization rates were more clearly
16 different (50% (7/14) and 21% (3/14) respectively), although this difference was not
17 significant ($p = 0.11$).

24
25
26
27
28
29
30

31 Due to the low number of mice included, this study only provides preliminary results.
32
33 Moreover, the uncertainty of reproduction in humans of what is demonstrated in
34 animals must be considered.
35
36
37
38

39 The iterative FMT allowed the eradication of CPE in 50% of colonized mice, which
40 can be considered as a moderately convincing result. In a recent study ⁶ conducted
41 with patients presenting blood disorders, the digestive carriage of NDM-1-producing
42 *Klebsiella pneumonia* was eradicated in less than 50% (6/14) of cases. In our
43 experiment, it is noteworthy that the decrease of the percentage of colonized mice
44 was higher in the FMT group than in the placebo group for each of the 4 treatment
45 series (figure 1). However, the short length of stay of most hospitalized patients limits
46 the applicability of a decolonization protocol including iterative FMT in the clinical
47 practice. However, it could be conceivable for patients hospitalized in long-term care

1 facilities or for the residents in nursing homes, in contexts of uncontrolled cross-
2 transmission during certain outbreaks of CPE carriage, and if the FMT are
3 administered orally. Additional studies are needed for evaluating the impact of the
4 composition of the transplanted fecal material on the FMT outcome in terms of CPE
5 eradication. Indeed, Ubeda et al.⁷ have recently demonstrated that intestinal
6 microbiota transplant containing *Barnesiella* species cured VRE colonization in mice.
