**Abstract:** Lipid nanocapsules (LNCs) are potential drug carriers for pulmonary delivery since they can be nebulized without any structural or functional changes, and the aerosols produced are highly compatible with pulmonary drug delivery in human beings. The alveolar surface tension, in vitro cytotoxicity, biodistribution and pulmonary toxicity in rats of a single endotracheal spray of LNCs or paclitaxel-loaded LNCs were studied. In vitro cytotoxicity of LNCs after a spray remained unchanged. Biodistribution study showed a homogeneous repartition in the lungs in rats with an improvement in lung retention of the radiolabeled tracer loaded in LNCs compared to the absence of LNCs with a lung half-time of  $8.8 \pm 0.7$  hours. Bronchoalveolar fluid analysis revealed transient 7-day alveolar inflammation, reaching a maximum between days 2 and 4, characterized by a peak of granulocytes at day 1 followed by a peak of lymphocytes at day 3. Alveolar protein levels were increased at days 3 and 7. Acute inflammation was increased with paclitaxel-loaded LNCs in comparison with blank LNCs but dropped out at day 7. No histological pulmonary lesion was observed at day 60. LNCs lowered surface tension to a greater degree than Curosurf® in a physicochemical model of the pulmonary alveolus. A single pulmonary delivery of LNCs induces a short-term alveolar inflammation with no residual lesions in rats at day 60. These data permit to start the study of LNCs in surfactant replacement therapy.

**Keywords:** lipid nanocapsules, pulmonary drug delivery, biodistribution, toxicity, paclitaxel

## Introduction

Lipid nanocapsules (LNCs) are nanometric vectors that can be used to dissolve lipophilic drugs without the need of organic solvents or excipients known to have a recognized effect.<sup>1</sup> They are versatile nano-sized drug carriers able to solubilize highly lipophilic drugs and to generate aerosols as paclitaxel (PTX) or fluticasone propionate.<sup>2,3</sup> The produced aerosols are compatible with pulmonary drug delivery in human beings, with an aerosol mass median aerodynamic diameter equal to  $2.7 \pm 0.1$   $\mu\text{m}$  and a fine particle fraction (between 1.0 and 5.0  $\mu\text{m}$ ) of  $81.5\% \pm 3.1\%$ .<sup>4</sup>

Pulmonary drug delivery presents a number of advantages to treat chronic lung diseases such as asthma, chronic obstructive pulmonary disease or cystic fibrosis, or acute diseases such as hyaline membrane disease in preterm neonates.<sup>5–8</sup> Aerosolized anticancer drugs have potential interests to treat lung adenocarcinoma or lung metastases.<sup>9</sup> The main advantages are direct access to the zones to be treated, allowing a reduction in the doses administered to the patient and consequently a reduction in systemic adverse effects. In addition, the pulmonary route has new interest in newborns, because it could reduce the potential interactions with the intestinal microbiota and could avoid interference with the immune development or the gut–brain axis.<sup>10–13</sup>

Preclinical toxicological data on LNCs obtained after intravenous administration in mice have demonstrated the good safety of these nanocarriers.<sup>14,15</sup> On the contrary,

published data on some pulmonary drug delivery systems have shown acute toxicity in mice. In fact, surface hydrophobicity of nanoparticles from 50 to 150 nm was characterized by hydrophobic interaction chromatography (HIC). The acute lung inflammation was quantified after pulmonary administration to mice. The correlation between nanomaterial HIC index and acute lung inflammation was determined for LNCs, polyvinyl acetate and polystyrene nanoparticles. This study showed that LNCs have a low HIC index and induce little inflammation unlike polyvinyl acetate and polystyrene nanoparticles characterized by high HIC index and increase acute alveolar toxicity.<sup>16</sup> In another study, the relationships between nanoparticle hydrophobicity, inflammatory outcomes and the metabolic fingerprint in bronchoalveolar fluid from mice exposed to various nanoparticles were studied following a single-dose intratracheal administration. Results confirm that particles with high surface hydrophobicity were proinflammatory and that adenosine monophosphate (AMP) concentration in bronchoalveolar fluid was correlated with neutrophilia and nanoparticle surface hydrophobicity.<sup>17</sup> Grabowski et al,<sup>18</sup> in a model of human respiratory alveolar epithelium cell culture, have clearly demonstrated that the inflammation and cell damage induced by these vectors are correlated with the surface charge and the nature of the nanoparticle core.

The purpose of this study was to determine the potential toxicity of a single endotracheal spray of LNCs in rats. We studied in vitro cytotoxicity of blank and PTX-loaded LNCs (PTX-LNCs), biodistribution and acute and middle-term pulmonary toxicities of blank and PTX-LNCs in rats after a single endotracheal spray. We also studied the alveolar surface tension of LNCs on a physicochemical model of the pulmonary alveolus.

## Materials and methods

### Materials

Lipoid® P75-3 (genetically modified organism-free soybean lecithin containing 69% of phosphatidylcholine), Captex® 8000 (glyceryl tricaprylate), Labrafac® CC (caprylic–capric acid) and Kolliphor® HS15 (polyethyleneglycol ester of 12-hydroxystearic acid and polyethylene glycol) were obtained from Lipoid GmbH (Ludwigshafen, Germany), Abitec Corp. (Columbus, OH, USA), Gattefosse SA (St-Priest, France) and BASF (Ludwigshafen, Germany), respectively. PTX powder and commercial Taxol® 6 mg/mL were provided by LC Laboratories (Woburn, MA, USA) and Bristol-Myers Squibb (Rueil-Malmaison, France), respectively. Distilled water was obtained from Cooper (Melun, France).

Sodium chloride (NaCl) was obtained from Prolabo VWR International (Fontenay-sous-Bois, France). Sterile saline serum was supplied by Aguettant (Lyon, France). Dichloromethane was supplied by Sigma-Aldrich Co. (St Louis, MO, USA). Phosphate-buffered saline (PBS) was obtained from Lonza (Verviers, Belgium). Ministar® 0.20 µm high-flow filters from Sartorius AG (Goettingen, Germany) were used. Cryo.S cryotubes were purchased from Greiner Bio-One (Frickenhäusen, Germany). About 4% phosphate-buffered formalin was obtained from Labonord (Templemars, France). <sup>99m</sup>Tc-pertechnetate (<sup>99m</sup>TcO<sub>4</sub><sup>-</sup>) was obtained by saline elution of a <sup>99</sup>Mo/<sup>99m</sup>Tc generator (IBA, Paris, France). Excipients for the formulation of the <sup>99m</sup>Tc-super six sulfur lipophilic complex were obtained from Chemical Engineering and Molecules for Life Sciences Platform (Rennes, France). Curosurf® was obtained from our academic pharmacy.

### LNCs

#### Preclinical batches of LNCs

The study was performed on LNCs having a mean diameter of 55 nm and prepared according to a scaled-up protocol that was compliant with the original process and allowed the production of standard batches for in vivo studies.<sup>1,4,19</sup> Briefly, Captex 8000, Lipoid S75-3, Kolliphor HS15, NaCl and water (12 g, 672 mg, 10 g, 733 mg and 18 g, respectively) were mixed and heated to 90°C under magnetic stirring. Three cycles of progressive heating and cooling between 90°C and 70°C were then carried out. Thermal exchanges were optimized by bathing in water at 95°C and at room temperature. This step was followed by an irreversible shock, induced by dilution with 112 mL of 0°C deionized water added to the mixture at a temperature of 78°C. Magnetic stirring was applied to the LNCs suspension for 5 minutes at room temperature, and molar sodium hydroxide and NaCl were added (50 µL and 110 mg, respectively). The dispersion was filtered through a 0.20 µm Ministar filter into a sterile CRYO.S cryotube. For the formulation of PTX-LNCs, 1.8% w/w of PTX powder was first solubilized in Captex 8000 under magnetic stirring and heated at 50°C for 30 minutes. The procedure described earlier was then applied to this mixture. CRYO.S cryotubes, previously filled with LNCs dispersion, were frozen in liquid nitrogen. Cryotubes were thawed at room temperature for 30 minutes before use. This procedure allowed to obtain a suspension with a concentration of 0.181 mg/mL of PTX.

#### Batches of radiolabeled LNCs

LNCs loaded with technetium-99m (<sup>99m</sup>Tc-SSS-LNCs) were obtained by means of a two-step procedure. The first step

consisted of preparation of a  $^{99m}\text{Tc}$ -SSS complex according to a previously described method.<sup>20</sup> Briefly, the  $^{188}\text{Re}$ -SSS complex was obtained by the reaction of the ligand sodium dithiobenzoate (Chemical Engineering and Molecules for Life Sciences Platform) with a freeze-dried formulation kit containing 30 mg of sodium gluconate, 30 mg of ascorbic acid, 40 mg of potassium oxalate and 4 mg of  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$  reconstituted in 0.5 mL of normal saline. About 1,110 MBq of  $^{99m}\text{Tc}$ -pertechnetate ( $^{99m}\text{TcO}_4^-$  in 0.5 mL) was added, and the solution was mixed for 15 minutes at room temperature. About 20 mg of sodium dithiobenzoate (in 0.5 mL, pH = 7) was then added before heating at 100°C for 30 minutes, resulting in the formation of the  $^{99m}\text{Tc}$ -SSS lipophilic complex. The second step consisted of encapsulation of the newly formed  $^{99m}\text{Tc}$ -SSS complexes in the lipophilic core of the nanocapsules. For this purpose, LNCs were prepared according to the phase inversion process described earlier.

### Characterization of LNCs

Size distribution, polydispersity index and zeta potential measurements of LNCs dispersions were characterized by photon correlation spectroscopy using a Malvern Zetasizer®, Nano Series DTS 1060 (Malvern Instruments, Malvern, UK). To determine the drug payload, PTX-LNCs dispersions were filtered through 0.22 µm Ministar high-flow filters. PTX concentrations and encapsulation efficiency were measured in the supernatant by high-performance liquid chromatography in triplicate experiments according to a previously described protocol.<sup>14</sup> The same experiments were performed with LNCs dispersions after formation of an aerosol.

### Formation of LNCs aerosols

Pulmonary nebulization of LNCs in rodents was generated by means of an endotracheal spray produced by a MicroSprayer® Aerosolizer – Model IA-1C-R (Penn-Century, Inc., Wyndmoor, PA, USA) according to a previously published method.<sup>21</sup> Briefly, after isoflurane-induced anesthesia, rats were suspended by their upper incisors. The tip of the MicroSprayer Aerosolizer was introduced into the animal's trachea using a pediatric laryngoscope. Aerosol deliveries were performed under a fume hood to avoid exposure of the operator. The aerosol was collected in a CRYO.S cryotube for analysis of the LNCs after passage in the MicroSprayer.

### In vitro cytotoxicity study

The in vitro cytotoxicity of thawed LNCs, "sprayed" and thawed LNCs, thawed PTX-LNCs and sprayed and thawed PTX-LNCs on NCI-H460 human lung cancer cells was

determined using a growth inhibition assay. A NCI-H460 human, large cell lung carcinoma cell line was obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA). Cells were cultured in RPMI 1640 medium containing glutamine (Lonza), 10 mM HEPES (4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid) (Sigma-Aldrich Co.), 1 mM sodium pyruvate (Lonza), 1.5 g/L sodium bicarbonate (Cambrex Biosciences, Verviers, Belgium), 10% fetal bovine serum (Lonza), 50 U/mL penicillin and 50 mg/mL streptomycin (Sigma-Aldrich Co.). Cells were routinely maintained at 37°C in a humidified atmosphere of 5%  $\text{CO}_2$  in air. The culture medium was replaced every 2 or 3 days, and the cells were subcultured weekly using 0.25% trypsin – 1 mM EDTA (Sigma-Aldrich Co.). Tumor cells were seeded in 24-well plates at 50,000 cells/well. All the assays were performed with exponentially growing cultures. A drug-containing medium was added after 48 hours. A dose range from  $10^{-3}$  to 100 nM PTX-LNCs or LNCs formulations was tested for each sample. Cytotoxicity was assessed after 2 days of exposure by adding 80 µL of CellTiter 96® Aq<sub>ueous</sub> One Solution Reagent (Promega Corporation, Fitchburg, WI, USA) to each well according to the manufacturer's instructions.<sup>22,23</sup> After 4 hours of culture, cell viability was determined by measuring the absorbance at 492 nm using a Multiskan Ascent microplate reader (Thermo Fisher Scientific, Waltham, MA, USA). As LNCs dispersions are not translucent, the absorbance of wells containing the cells was subtracted from the absorbance of wells containing culture medium alone for each point. The half-maximal inhibitory concentration ( $\text{IC}_{50}$ ) of the drug was calculated. Three independent experiments were performed in triplicate.

### Animal studies

Experiments were performed in 180 female, 8–10-week-old Sprague–Dawley rats weighing 200–300 g (Janvier Labs, Le Genest Saint Isle, France) housed in the Angers University Hospital animal facility. Animals were provided with food and drinking water ad libitum according to a regular 12-hour day/night cycle. After 1 week of acclimatization, animals were randomized to experimental groups. Following randomization, animals were observed and weighed daily. Weight loss, the appearance of the fur, respiratory rate, behavior and responses to normal stimuli were evaluated daily according to the toxicity scale described elsewhere.<sup>14</sup> For each animal, a single daily endotracheal spray of 200 µL was administered during brief isoflurane anesthesia according to a validated protocol.<sup>21</sup> This volume corresponds to a surface area dose of ~2,650 cm<sup>2</sup> per animal. The research complied with

the European Community guidelines for the protection of animals used for scientific purposes. The experimental protocol was approved by the Pays de la Loire ethics committee on animal experiments (number 2011.9), and studies were conducted in compliance with French legislation.

### Biodistribution study

Six female Sprague Dawley rats were housed in individual metabolism cages for the collection of urine and feces. For the biodistribution studies, 15 MBq of the LNCs- $^{99m}\text{Tc}$ -SSS suspension ( $n=4$ ) or the  $^{99m}\text{Tc}$ -pertechnetate solution ( $^{99m}\text{TcO}_4^- \text{Na}^+$ ) as control ( $n=2$ ) was administered by the endotracheal spray technique (15 MBq/200  $\mu\text{L}$ ) in xylazine- and isoflurane-anesthetized healthy Wistar rats. Static acquisitions were obtained at the times 10 minutes, 1 hour, 3 hours and 22 hours using a SOPHA DSX  $\gamma$ -camera (Sopha Medical Vision, Buc, France) dedicated to animal studies. A scout view was acquired on a GE LightSpeed system (GE Healthcare UK Ltd, Little Chalfont, UK) and fused with the planar scintigraphy of the same animal for anatomical localization of the LNCs- $^{99m}\text{Tc}$ -SSS and the  $^{99m}\text{TcO}_4^-$  distributions. For this purpose, the acquired images were analyzed and processed on a Xeleris 2 workstation (GE Healthcare). Regions of interest (ROIs) were drawn manually on various organs (lungs, liver, stomach, spleen, trachea) on the planar images. Time-activity curves for the LNCs- $^{99m}\text{Tc}$ -SSS- and the  $^{99m}\text{TcO}_4^-$  control-injected rats were obtained by plotting the ROIs on the images for the various acquisition times. The activity in the ROI was expressed as a percentage of the injected dose. To compare the lung clearance (Cl) kinetics of the LNCs- $^{99m}\text{Tc}$ -SSS and the  $^{99m}\text{TcO}_4^-$  controls, several pharmacokinetic parameters such as lungs' half-life ( $T_{1/2}$ ), mean residence time (MRT) and Cl were calculated using a non-compartmental model for the analysis of the pharmacokinetics data (Kinetica 5.1 software; Thermo Fisher Scientific).

### Lung wet/dry weight and lung/body weight ratios and histological examination

Exploratory analysis of lung wet/dry weight and lung/body weight ratios was designed to determine the duration and intensity of any pulmonary inflammation induced by the various aerosols.<sup>24</sup> Animals were randomized in 19 groups of six rats: one control group receiving no spray, six groups receiving one saline serum spray, six groups receiving one blank LNCs spray and six groups receiving one PTX-LNCs spray. A batch of animals from each group was sacrificed on days 1 (24 hours after endotracheal spray), 2, 4, 7, 21 and 60. Each animal was weighed before sacrifice, and the fresh weight of the lungs

was determined after sacrifice. Necropsy (thorax + abdomen + pelvis) was performed on each animal at the time of sacrifice. Light microscopy histological examination of the lungs was performed on the animals of the three groups sacrificed on day 60. Lungs were fixed in 50% formalin for histological examination. About 5  $\mu\text{m}$  paraffin-embedded and hematoxylin-eosin-saffron-stained sections were analyzed according to a previously published score.<sup>14</sup> This score assessed lung inflammation in four lung sectors: peribronchiolar, perivascular, interstitial and alveolar. For each sector, the histopathological aspect was scored on a scale of 0 (no change: normal aspect), 1 (mild inflammation: dispersed mononuclear leukocytes), 2 (moderate inflammation: presence of one to three nodules of mononuclear leukocytes) and 3 (severe inflammation: more than three nodules of mononuclear leukocytes). The final score was the sum of the highest scores observed in each sector of the lungs. The researchers who examined the slides were blinded to the treatments received by the rats. A total of 114 animals were included in this study.

### Bronchoalveolar lavage (BAL) examination

Animals were randomized to 10 groups of six rats: one control group receiving no spray, three groups receiving one saline serum spray, three groups receiving one blank LNCs spray and three groups receiving one PTX-LNCs spray. BAL was performed on a batch of animals from each group on days 1 (24 hours after endotracheal spray), 3 and 7. After sacrifice by inhalation of 5%  $\text{CO}_2$ , BAL was performed on both lungs in the following way: the trachea was surgically exposed and incised transversely to introduce a metal cannula with a watertight seal. Two aliquots of 7.5 mL of PBS were then injected. The fluid was re-aspirated with the syringe. BAL fluid was then centrifuged at 1,500 rpm at 4°C, and the pellet was recovered and suspended in 250  $\mu\text{L}$  of PBS. Global alveolar cellularity was determined by counting on a Malassez cell. The differential cell count was determined after centrifugation and smearing on a slide with a Cytospin 4 and Hematoxylin-Eosin-Saffron (HES) staining. At least 100 cells were counted to determine the proportion of macrophages, neutrophils, eosinophils and lymphocytes. The lipid index of foamy macrophages was calculated according to Hopkins et al.<sup>25</sup> Briefly, Oil red O staining was performed in BAL cells. The red vacuoles of 100 consecutive macrophages were scored from 0 to 4 (0: absence of staining, 1: presence of one to three intracellular distinct lipid droplets, 2: more than three distinct lipid droplets, 3: multiple confluent droplets with visible nucleus, 4: complete opacifications of the cytoplasm with obscuration of the nucleus). The lipid

index was computed as the summation for all scores. The researchers who examined the slides were blinded to the treatments received by the 60 rats. The supernatant was collected for the assay of total alveolar protein by the BCA protein assay kit (Pierce Biotechnology, Rockford, IL, USA) according to the manufacturer's instructions.

## Study of alveolar surface tension

Alveolar surface tension was studied by means of a pendant-drop tensiometer (Tracker; IT Concept, Longessaigne, France) based on the captive bubble model.<sup>26–28</sup> The 5  $\mu\text{L}$  bubble was immersed in a saline bath at 37°C. Surface tension was measured under static conditions for 3 minutes to determine the equilibrium surface tension and the time required to achieve this equilibrium for four solutions: saline; 50  $\mu\text{g/mL}$  Curosurf; 50  $\mu\text{g/mL}$  Kolliphor HS15 or LNCs at a concentration equivalent to 50  $\mu\text{g/mL}$  of Kolliphor HS15. Equilibrium adsorption data are expressed as time, and minimum surface tension is expressed in mN/m. The results of three independent experiments are presented (mean  $\pm$  SD).

## Statistical analysis

Results are expressed as mean  $\pm$  SD. A Kruskal–Wallis test was used to determine statistical significance, completed by a Mann–Whitney *U*-test. In every case,  $p < 0.05$  was considered to be significant. SPSS version 19 software (IBM Corporation, Armonk, NY, USA) was used for statistical analysis.

## Results

### Characteristics of batches of LNCs

The structural characteristics of blank LNCs and PTX-LNCs after thawing and passage in the MicroSprayer Aerosolizer are presented in Table 1. The mean particle sizes of thawed blank LNCs, thawed and sprayed blank LNCs, thawed PTX-LNCs, thawed and sprayed PTX-LNCs and radiolabeled

LNCs were 65.5, 65.6, 65.2, 65.0 and 55.9, respectively. The polydispersity indexes of thawed blank LNCs, thawed PTX-LNCs and radiolabeled LNCs were 0.039, 0.039 and 0.038, respectively. These indexes were increased to 0.126 and 0.107 after passage in the MicroSprayer Aerosolizer for thawed blank LNCs and thawed PTX-LNCs, respectively. The zeta potentials of the dispersions were found between  $-6.9$  and  $-9.3$  mV. For drug-loaded nanocarriers, the PTX payload was equal to  $1.6 \pm 0.1$  mg/mL after thawing and remained unchanged after passage in the MicroSprayer Aerosolizer.

## In vitro cytotoxicity study

The results of cytotoxicity assays are presented in Figure 1 and Table 1. The  $\text{IC}_{50}$  of PTX was 3.1 nM, as published elsewhere (4.8 nM).<sup>29</sup> The  $\text{IC}_{50}$  values of thawed blank LNCs, thawed and sprayed blank LNCs, thawed PTX-LNCs and thawed and sprayed PTX-LNCs were 2.1, 2.1, 2.4 and 2.3 nM, respectively.

## Animal studies

The endotracheal spray procedure did not induce any mortality. All animals resumed a normal behavior immediately after waking. No pathological respiratory or general signs were observed in the animals. The daily toxicity score was equal to 0 for each rat on each day. Weight gain was observed in all the animals after administration of the spray until the day of sacrifice, with no significant difference between the groups. In view of the concentration of the LNCs formulations, the administration of 200  $\mu\text{L}$  of spray corresponds to a mass dose

**Table 1** Characterization of LNCs batches

Formulation group	Mean particle size (nm)	Polydispersity index	Zeta potential (mV)	$\text{IC}_{50}$ (nM)
Thawed blank LNCs	65.5 $\pm$ 0.2	0.039 $\pm$ 0.005	$-6.9 \pm 0.3$	2.1
Thawed and sprayed blank LNCs	65.6 $\pm$ 2.5	0.126 $\pm$ 0.008	$-8.4 \pm 0.2$	2.1
Thawed PTX-LNCs	65.2 $\pm$ 0.8	0.039 $\pm$ 0.005	$-7.9 \pm 0.3$	2.4
Thawed and sprayed PTX-LNCs	65.0 $\pm$ 0.4	0.107 $\pm$ 0.007	$-7.8 \pm 0.9$	2.3
Radiolabeled LNCs	55.9 $\pm$ 0.6	0.038 $\pm$ 0.008	$-9.3 \pm 0.6$	–

**Note:** This result shows that the  $\text{IC}_{50}$  is equal.

**Abbreviations:**  $\text{IC}_{50}$ , half-maximal inhibitory concentration; LNCs, lipid nanocapsule; PTX, paclitaxel; PTX-LNCs, PTX-loaded LNCs.

of  $\sim 36 \mu\text{g}$  per animal and a surface area of about  $\sim 2,650 \text{ cm}^2$  for the two lungs.

### Biodistribution study

Only a low level of the radioactivity deposition in the trachea ( $6.08\% \pm 1.14\%$  and  $11.15\% \pm 2.99\%$ , respectively) was observed following the endotracheal administration of the LNCs- $^{99\text{m}}\text{Tc}$ -SSS ( $n=4$ ) or the  $^{99\text{m}}\text{TcO}_4^-$  solution ( $n=2$ ). As expected, 10 minutes after the administration of the LNCs- $^{99\text{m}}\text{Tc}$ -SSS or the  $^{99\text{m}}\text{TcO}_4^-$ , the static planar scintigraphic acquisitions combined with scout scans revealed distribution of both tracers in the lungs. However, subsequent acquisitions (1, 3 and 22 hours post injection) showed dramatic changes between the distribution of the LNCs- $^{99\text{m}}\text{Tc}$ -SSS and the  $^{99\text{m}}\text{TcO}_4^-$  (Figure 2A and B). Time-activity curves extracted from the scintigraphic acquisition provided details regarding tracer distribution kinetics following endotracheal administration (Figure 3). Lung CI kinetics of LNCs- $^{99\text{m}}\text{Tc}$ -SSS appeared to be slow with a lung  $T_{1/2}$  of  $8.8 \pm 0.7$  hours, an MRT of  $12.9 \pm 0.9$  hours and a CI of  $0.087 \pm 0.007 \text{ h}^{-1}$  (Figure 3A), whereas the lung CI of  $^{99\text{m}}\text{TcO}_4^-$  was significantly faster with

a  $T_{1/2} = 3.4 \pm 1.0$  hours ( $p=0.0013$ ), an MRT of  $4.9 \pm 1.4$  hours ( $p=0.001$ ) and a CI of  $0.273 \pm 0.068 \text{ h}^{-1}$  ( $p=0.0036$ ; Figure 3B). The lung CI of the LNCs- $^{99\text{m}}\text{Tc}$ -SSS was concomitant with an increase in radioactivity in the liver. In contrast, the stomach was the first elimination organ detected after the CI of the  $^{99\text{m}}\text{TcO}_4^-$  from the lungs.

### Animal's lung wet/dry weight and lung weight/body weight ratios

The lung wet/dry weight ratios were not significantly different between the groups from day 1 to 60 (data not shown). The study of the animal's lung weight/body weight ratio is shown in Figure 4. This ratio was significantly higher in the blank NCL spray and PTX-LNCs spray groups by day 1 compared to the control group. This increased ratio reached a maximum between days 2 and 4 and returned to normal on day 7 and was comparable to that observed in the control group on days 21 and 60. By applying the rule of three Rs to animal experimentation, we therefore decreased the number of animal analyses by removing the day 21 and day 60 groups and by pooling the day 2 and day 4 groups into a single day 3 group for BAL examinations.

### BAL fluid analysis

The median volume of BAL fluid recovered from lavaged rat lungs was  $13.5 \pm 0.5 \text{ mL}$ , and no difference was observed between groups and days. All BAL fluids were clear. The total alveolar cell count is shown in Figure 5. A significantly higher total alveolar cell count was observed in the PTX-LNCs spray group compared to the control group on days 1 and 3. The alveolar differential cell count is described in Table 2. No eosinophil was observed in BAL. An increased proportion of granulocytes (neutrophils) was observed on day 1 in all the groups compared to the control group. The highest proportion of granulocytes was observed in the PTX-LNCs spray group. On day 3, the proportion of granulocytes decreased and the proportion of lymphocytes then increased. On day 7, the proportions of the various cells returned to baseline. Three examples of BAL are shown in Figure 6. Foamy macrophages were observed since day 1 but were no longer seen on day 7. Lipid index was calculated on days 1 and 3 (Figure 7). Examples of foamy macrophages are shown in Figure 8. Total protein assay is illustrated in Figure 9. Results indicate an increase in the total alveolar cells on the PTX-LNCs spray group only at day 1.

### Necropsy and long-term histological examination

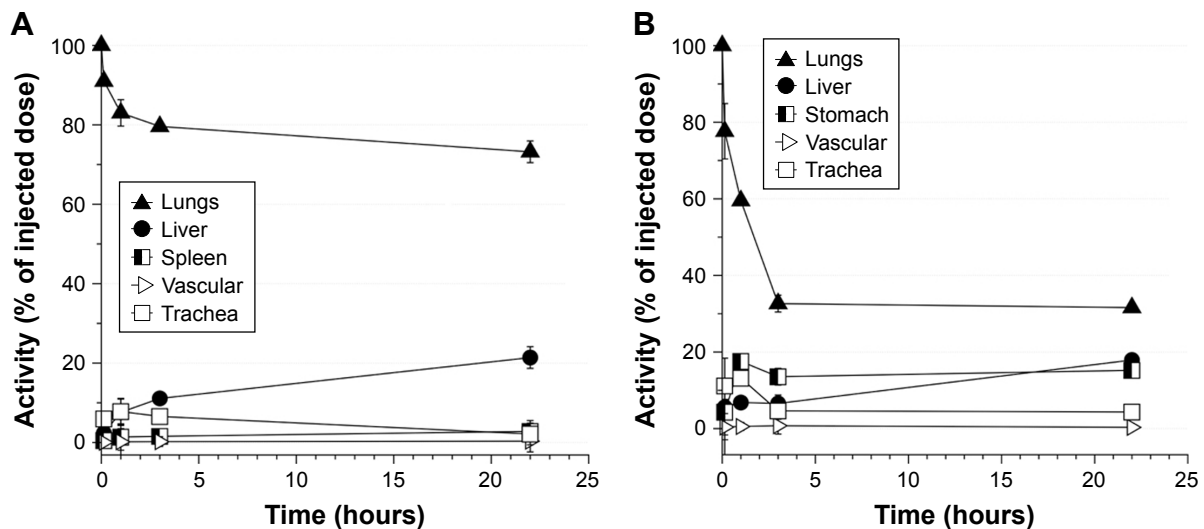

Follow-up of the animals until day 60 did not demonstrate any clinical or behavioral abnormalities. No macroscopic

**Figure 2** Scout view on a GE LightSpeed system fused with the planar scintigraphy of the same animal for the anatomical localization of the LNCs- $^{99\text{m}}\text{Tc}$ -SSS (A) and the  $^{99\text{m}}\text{Tc}$ -pertechnetate distributions (B) at 10 minutes, 1 hour, 3 hours and 22 hours following the unique endotracheal spray technique administration.

**Notes:** The successive acquisitions showed the lung distribution of the LNCs- $^{99\text{m}}\text{Tc}$ -SSS (A) and a lung CI significantly slowed compared to the control (B). The extra-pulmonary distribution of the LNCs- $^{99\text{m}}\text{Tc}$ -SSS is considerably reduced compared to the control.

**Abbreviations:** CI, clearance; LNCs, lipid nanocapsule.

**Figure 3** Time-activity curves for LNCs-<sup>99m</sup>Tc-SSS (A) and <sup>99m</sup>Tc-pertechnetate control-injected rats (B).

**Notes:** The error bars are too small to be seen over the time. These curves showed a lung retention of activity with LNCs, whereas there was a faster CI with the controls. Vascular corresponds to an ROI on the thigh muscle.

**Abbreviations:** CI, clearance; LNCs, lipid nanocapsule; ROI, region of interest.

abnormality of the lungs, heart, kidneys, liver, spleen, ovaries or gastrointestinal tract was observed on necropsy examinations. No lymph node hypertrophy or pleural, pericardial or peritoneal effusion was observed. Histological examination of the lungs removed on day 60 did not reveal any signs of pulmonary toxicity according to a previously published histopathological score (Table 3).<sup>14</sup> Typical pulmonary lesions are shown in Figure 10.

**Figure 4** Mean  $\pm$  SD of lung/body weight ratio for the control group (no spray), the saline serum spray group, the blank LNCs spray group and the PTX-LNCs spray group at days 1, 2, 4, 7, 21 and 60 (n=6).

**Notes:** Results indicate an increase in the ratio at days 1, 2 and 4 in the blank LNCs and PTX-LNCs groups. At days 7, 21 and 60, no difference is observed. \* $p < 0.05$  versus the control group. \*\* $p < 0.01$  versus the control group.

**Abbreviations:** LNCs, lipid nanocapsule; PTX, paclitaxel; PTX-LNCs, PTX-loaded LNCs.

## Surface tension analysis

Analysis of alveolar surface tension is shown in Figure 11. The surface tension on the captive bubble was not modified by the addition of saline. The addition of Kolliphor HS15 (50  $\mu$ g/mL) and Curosurf (50  $\mu$ g/mL) lowered captive bubble surface tension from about  $70.3 \pm 0.4$  to  $47.4 \pm 0.5$  and  $46.2 \pm 0.4$  mN/m after 360 seconds, respectively. The addition of LNCs, at a concentration equivalent to 50  $\mu$ g/mL of Kolliphor HS15, lowered captive bubble surface tension

**Figure 5** Mean  $\pm$  SD of total alveolar cells for the control group (no spray), the saline serum spray group, the blank LNCs spray group and the PTX-LNCs spray group at days 1, 3 and 7 (n=6).

**Notes:** Results indicate an increase in the total alveolar cells on the PTX-LNCs spray group only at days 1 and 3. At day 7, no difference is observed. \*\* $p < 0.01$  versus the control group.

from about 70 to  $42.0 \pm 0.5$  mN/m after 360 seconds ( $p < 0.05$  versus Kolliphor HS15 and Curosurf).

## Discussion

In this study, we studied the pulmonary drug delivery of a single endotracheal spray of LNCs or PTX-LNCs in rats. This study compiles data on the in vitro cytotoxicity analysis of LNCs and PTX-LNCs after spray generation by a MicroSprayer Aerosolizer, the biodistribution of LNCs after a spray in rats' lungs, the alveolar toxicity of a single endotracheal spray in rats of LNCs and PTX-LNC and the 60-day toxicity analysis. Exploratory study of the surfactant potential of LNCs on a physicochemical model of the pulmonary alveolus is also described. The results are the absence of structural degradation or loss of cytotoxicity of LNCs and PTX-LNCs after passage in a MicroSprayer Aerosolizer, a predominant biodistribution of LNCs in the lungs of the rats with a lungs' half-life of  $8.8 \pm 0.7$  hours, a CI of  $0.087 \pm 0.007$  h<sup>-1</sup> after pulmonary delivery, an initial and transient alveolar inflammation reflected by hypercellularity and increased total proteins in BAL fluid and the absence of

lung tissue lesions observable under light microscopy 60 days after a single endotracheal dose.

We first confirm previous results concerning the ability of LNCs to remain structurally and functionally unchanged after aerosol generation with the MicroSprayer Aerosolizer.<sup>16</sup> This procedure has been used in many studies to reproducibly deposit a large volume of solution of interest in the deep lung of rodents.<sup>21,30,31</sup> The volume of 200  $\mu$ L was chosen, because it corresponds to the maximum volume that can be administered to rats. This procedure was well tolerated and did not cause any death.

Instead of the classical ex vivo studies, a noninvasive approach, based on sequential planar scintigraphic imaging, was preferred to monitor, after endotracheal administration, the <sup>99m</sup>Tc-LNCs-SSS biodistribution. This method was chosen on the basis of a preliminary unpublished study, which showed that >90% of the radiolabeled LNCs remained localized in the lungs after a single spray. In this study, early acquisitions (t=10 min) confirmed the good performance of the endotracheal technique for the administration of the LNCs suspensions. Lung deposition appeared to be more effective,

**Figure 6** BAL smears after fixation and HES staining (40 $\times$ ).

**Notes:** (A) Control group rat: the cells are predominantly macrophages. (B) In a rat, 24 hours after PTX-LNCs spray: numerous granulocytes (arrows). All granulocytes were polymorphonuclear neutrophils. (C) In a rat 72 hours after PTX-LNCs spray: marked regression of the granulocyte population and appearance of lymphocytes (arrowheads). Stars indicate foamy macrophages.

with far less mouth or throat deposition, as compared to the administration technique by oral aspiration.<sup>32</sup> The lungs' time-activity curves revealed the slow pulmonary CI of LNCs and confirmed the potential value of LNCs to deliver drugs of interest into the deep lung. This slow lung CI of radioactivity was not observed with the control animals (>70% versus 32% of the dose is still present in the lung at  $t=22$  hours). Moreover, the discrepancies in organ biodistribution between the  $^{99m}\text{Tc}$ -LNCs-SSS and the controls clearly demonstrate the effect of LNCs on the behavior of the drug (ie,  $^{99m}\text{Tc}$ ).

**Figure 8** Oil red O staining of three macrophages from BAL at day 1 in the PTX-LNCs spray group (immersion,  $\times 100$ ).

**Note:** Each macrophage was scored at 3.

**Abbreviations:** BAL, bronchoalveolar lavage; LNCs, lipid nanocapsule; PTX, paclitaxel; PTX-LNCs, PTX-loaded LNCs.

Indeed, after the lung CI,  $^{99m}\text{TcO}_4^-$  control animals showed an accumulation of the tracer in the stomach (which is a classic uptake organ for  $^{99m}\text{TcO}_4^-$ ), whereas  $^{99m}\text{Tc}$ -LNCs-SSS showed only an accumulation in the liver, which indicates that a portion of LNCs (ie, 21.4% at  $t=22$  hours) was able to cross the air-blood barrier and reach the systemic circulation before its uptake by mononuclear phagocytic system (MPS) organs such as liver.

**Figure 9** Mean  $\pm$  SD of total proteins for the control group (no spray), the saline serum spray group, the blank LNCs spray group and the PTX-LNCs spray group at days 1, 3 and 7 ( $n=6$ ).

**Notes:** Results indicate an increase in the total alveolar cells on the PTX-LNCs spray group only at day 1. At days 3 and 7, no difference is observed. \* $p<0.05$  versus the control group.

The low level of the extrapulmonary distribution should reduce the risk of systemic toxicity. Patel et al<sup>32</sup> studied this parameter in mice and showed that 50 nm LNCs administered by oral aspiration were retained by the lungs with a half-life of 10.5 hours (which is consistent with our results) and that moderate pulmonary inflammation did not reduce the pulmonary CI of LNCs.

This study mainly focused on the detection of tissue lesions, such as pulmonary fibrosis, 60 days after endotracheal spray of LNCs in rats, as the absence of such lesions provides essential information in terms of preclinical safety. We looked for signs of acute alveolar inflammation by means of three parameters: lung weight/body weight ratio, changes in alveolar cell populations and changes in total alveolar proteins, reflecting tissue edema, cell influx and alveolar injury, respectively. We then performed light microscopy examination of the lungs to determine whether this inflammation resolved without leaving any tissue “sequelae” or whether it progressed to chronic inflammation. We did not study the immunological mechanisms involved in this inflammation (immune cell populations, cytokines and interleukin networks). This study is important, as particles with a large surface area/mass ratio can induce local toxicity via tissue inflammation, which can then induce tissue fibrosis. Jones et al<sup>16</sup> published the first toxicity study after pulmonary administration of 25 µL of 50 nm LNCs at a dose of 0.8 or 8 mg/mL per lung in mice. This study showed no changes in alveolar cell populations and an increase in total alveolar

proteins at the highest dose 24 hours after endotracheal spray delivered by a MicroSprayer Aerosolizer. Unlike Jones et al, we observed signs of alveolar inflammation, and this difference can be explained by the choice of the dose administered and the choice of animal species. We used undiluted LNCs and PTX-LNCs formulations, corresponding to a more than 10-fold higher surface area dose than the highest concentration used by Jones et al.<sup>16</sup> This concentration difference could explain the absence of toxicity in the study by Jones et al and the presence of toxicity in our study. We chose such a high concentration, because highly concentrated solutions allow the use of small nebulization volumes, resulting in shorter nebulization times for the patient. We have shown that the only commercial apparatus able to nebulize LNCs is the eFlow<sup>®</sup> rapid.<sup>4</sup> This apparatus has a 3 mL reservoir and takes 8.4 minutes to nebulize the volume of LNCs used in this study. We believe that the concentrations used in the studies by Jones et al were too low compared to the doses of

**Figure 11** Evolution of surface tension on the captive bubble versus time after the addition of saline serum, 50 µg/mL of Curosurf<sup>®</sup>, 50 µg/mL of Kolliphor<sup>®</sup> HS15 and LNCs at a concentration equivalent to 50 µg/mL Kolliphor HS15.

**Notes:** Isotherms were obtained by monitoring adsorption of the mixtures in the captive bubble tensiometer at 37°C. Data are mean ± SD of three independent experiments. The error bars are too small to be seen over the time. \**p* < 0.05 versus the Kolliphor HS15 and Curosurf. This figure illustrates the greater capacity of LNCs to reduce the surface tension on the captive bubble than Curosurf and Kolliphor HS15 alone.

**Abbreviation:** LNCs, lipid nanocapsule.

LNCs required in aerosol therapy. Furthermore, in contrast to Jones et al who took mice, our studies were conducted in rats, as the Organization for Economic Cooperation and Development recommends conducting acute lung toxicity studies in 8–12-week-old rats that have been acclimatized for at least 5 days.<sup>33</sup> Rats appear to be more sensitive than mice or hamsters to the risk of pulmonary fibrosis.<sup>34</sup> Our decision to perform this study in rats was therefore well adapted to the objective of this study.

In this study, we minimized the causes of exogenous pulmonary inflammation. We removed the excess of Kolliphor HS15 stabilizer by 0.22 µm filtration, which also allowed sterilization of the final LNCs and PTX-LNCs solutions before storage. Sterile normal saline was also used. We have previously demonstrated the pyrogen-free nature of the LNCs formulation.<sup>4</sup> Despite these precautions, it is noteworthy that simple endotracheal spray of normal saline induced a transient alveolar inflammatory reaction on day 1 in the rats of the saline serum group. The results of this study appear to justify the initiation of chronic toxicity studies in rats, which must look for the presence of chronic inflammation, pulmonary fibrosis and lipid accumulation. We did not investigate possible accumulation of lipids in the lungs, as lipid accumulation requires chronic exposure to inhaled lipids. We observed a higher proportion of foamy macrophages in the blank LNCs and PTX-LNCs groups than in the control and saline serum spray groups on day 1. The proportion of foamy macrophages then decreased on day 3, and they were no longer visible on day 7. These findings demonstrated progressive elimination of part of the lipids delivered in the aerosol by alveolar macrophages over the 7 days following endotracheal spray. Furthermore, Patel et al<sup>32</sup> showed that the alveolar inflammation induced by LNCs did not modify the pulmonary CI of these particles in mice, and therefore did not increase the risk of accumulation of the components of LNCs, particularly lipids, following the administration of a single dose.

Finally, we confirm that LNCs have surfactant property.<sup>35</sup> We demonstrated that this property was more effective than the tensio-active component alone of the LNCs (Kolliphor HS15) and the commercial animal-derived surfactant Curosurf.

## Conclusion

A single pulmonary delivery of blank LNCs or PTX-LNCs induces a short-term alveolar inflammation with no residual lesions in rats at day 60. These results indicate that LNCs is a potential drug carrier for pulmonary delivery of PTX.
