The TET2 Expression Level Correlates with a Short Relapse Time in Glioblastoma Multiforme

Abstract

Background: Epigenetic changes play crucial roles in cancer initiation and progression and in tumor recurrence. Glioblastoma multiforme (GBM) is by far the most common and most malignant of the glial tumors, and its recurrence is ineluctable. Thus, anti-GBM therapy need for new treatments for recurrent GBM. We here in focused on identifying whether TET2 (an epigenetic players involving in the DNA demethylation process) as a putative target for the development of anti-GBM therapy.

Results: We observed that the expression level of TET2 at mRNA and protein levels is not associated with a prognosis value of survival in GBM patients. However, in a cohort of 10 GBM patients having received two surgical resections (rGBM), we noted that three in ten rGBM patients have an increase of TET2 expression between resection#1 and #2.

Conclusions: By observing an increase of TET2 expression between two surgical resections an despite the fact that expression level of TET2 is devoid of prognosis value of survival in GBM patients, our data provide a promising starting point for the use of TET2 inhibitors administrable in the subgroup of patients with recurrent GBM.

Keywords: DNA methylation; TET; TET2; Glioblastoma multiforme; TET inhibitors

Introduction

The Ten-Eleven Translocation-2 (TET2) is a member of the TET family proteins that include 2 other members: TET1 and TET3. These proteins catalyze the steps of the active DNA cytosine-demethylation via the conversion of 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC), 5-formylcytosine (5fC) and 5-carboxycytosine (5CaC) [1-3]. TET2 such as other TET proteins is an α-ketoglutarate- and Fe²⁺-dependent dioxygenase and the oncometabolite 2-hydroxoglutarate inhibits its activity [4].

In cancer, the TET2 mutational state is frequently associated with a prognosis value. However, TET2 mutations are more present in liquid tumors than in solid tumors. As example, TET2 mutations are rare in breast, ovarian, lung and brain cancers and observed with a prevalence of 6%-26% in MDS, or in 12-27% in adult AML [5]. In glioblastoma multiforme (GBM), 7 genetic alterations within TET2 (p.V218M, p.G355N, p.P363L, p.L1721W, p.P1723S, p.I1762V, p.H1778R), are described, but the presence of these alterations was not associated with a prognosis value [6]. Investigations performed with human samples and murine models suggest that TET2 deficiency does not promote the tumorigenesis but predisposes to the development of certain tumors such as MPN, MDS and lymphoma [7]. In other terms, these works suggest that TET2 could act as tumor suppressor gene [8-10]. However, TET2 could act as an oncogene by
participating to the global DNA hypomethylation phenotype i.e. oncogenic phenotype. A recent article suggests that TET2 sustains immunosuppressive function of tumor-infiltrating myeloid cells to promote melanoma progression [11]. Thus, this last article supports the idea that TET2 could be a therapeutic target in certain cancers (other than hematologic cancer, certainly).

The role of TET proteins in glioblastoma multiforme is not fully documented. Two articles report the involvement of TET3 in GBM. Cui et al. suggest that TET3 acts as a tumor suppressor gene in glioblastoma stem cells [12]. Two articles report that TET3 is involved in the dynamic methylation/demethylation mechanism in GBM cells [13,14]. Takai et al. report that TET1-mediated production of 5-hydroxymethylcytosine (5hmC) is required for the tumorigenicity of glioblastoma cells [15]. The nuclear exclusion of TET1 is also reported as a source of DNA methylation and a loss of 5-hydroxymethylcytosine [16]. However, the large majority of articles investigating the role of TET1 in glioma is focused on low-grade glioma. A similar observation can be performed about TET2 [17,18]. Chen et al. reports that the modulation of TET2 expression affects the invasion potential and the proliferation rate of glioma cells [19]. Always in low-grade glioma, Guilhamon et al. report that TET2 interacts with EBF1 to promote a sequence-specific mechanism of DNA demethylation [20]. Thus, there is a lack of investigation on the role of TET2 on GBM. In order to try to overcome this deficiency, our present study investigated the putative association of TET2 with a prognosis value in the context of GBM and its dynamic expression following first resection and standard anti-GBM treatment.

Methods

Tumors samples

Tumors were collected from the “Réseau des tumorothèques du Canceropole Grand-Ouest/réseau Gliome”, the “Base clinico-biologique des Glioblastomes (n°BRIF: BB-0033-00093), CHU Angers, France” and the Biological Resource Center of University hospital of Angers. Tumor patient material and records (diagnosis, age, sex, date of death) were used with confidentiality in accordance with French laws and the recommendations of the French National Ethics Committee. In accordance with the regulations, all subjects signed a specific informed consent form for this biocollection, approved by an Ethics Committee, the French State Department for National Education, Higher Education and Research and the CNIL.

Protein analysis: ELISA

Proteins extracts were obtained by using RIPA Lysis and Extraction Buffer (Thermo Scientific, France) in accordance with the manufacturer’s instructions. TET2-ELISAs were performed according to the manufacturer’s instructions (MyBiosource, MBS9317739, USA).

Statistics

The log-rank test was used to test whether the difference between survival times of two groups is statistically different or not. The Kaplan-Meier survival curves were used to represent the probability of surviving in a given length of time of subgroups of patients. T-test is performed to estimate whether the difference between a parameter characterizing two groups is statistically different or not. Pearson’s correlation test is performed to estimate the significant character of a correlation between two parameters.

Results

The TET2mRNA level is not associated with a prognosis value

To investigate whether TET2mRNA can be used as a biomarker associated with a favorable survival, we first analyzed data available on “Betastasis/REMBRANDT database” (http://www.betastasis.com/glioma/rembrandt/kaplan_meier_survival_curve/). Thus, we observed that the expression level of TET2mRNA in GBM is not associated with a prognosis value of survival, neither in term of overall survival (OS) (Figure 1).

The TET2 expression level is not associated with a prognosis value

In a second approach, we have considered the TET2 protein expression level as a putative biomarker associated with a prognosis survival. TET2 expression level was analyzed in 31 GBM patients. The patients’ characteristics of this cohort (cohort#1) are listed in (Table 1). ELISA was performed to calculate the TET2 expression level in GBM (Figure 2A). Our data indicates significant heterogeneity in the TET2 expression since a 11-fold increase was observed between the minimal value and the maximal value for TET2.

Then, our cohort of 31 GBM samples has been divided in 2 subgroups using the median value as threshold. Survival curves were visualized in Kaplan-Meier plot. A log-rank test indicates a lack of difference between the overall survival of GBM patients having a high level of TET2 and those having a low level of TET2 (Figure 2B).

The TET2 expression level correlates with a short relapse time in recurrent GBM

We extended our study by asking if the TET2 expression could be...
associated with a short relapse time in recurrent GBM (rGBM). To address this question, TET2 expression level was analyzed by ELISA in resection #1 and #2 of 10 GBM patients having received two surgeries. The relapse time is here defined such as the months separating the both resections. The patients’ characteristics of this cohort (cohort #2) are listed in Table 1. All GBM of this cohort are IDH1 wild-type and are primary GBM (i.e. that the patients are devoid of medical history with low grade glioma). Thus, we noted that three in ten rGBM patients have an increase of TET2 expression between resection #1 and #2 (Figure 3A). One in ten rGBM patients harbors a decrease of TET2 expression (Figure 3A). We next calculated the changes of TET2 expression between resection #1 and #2 (#TET2= TET2Resection#2 - TET2Resection#1). Graph and Pearson’s correlation test indicate that the changes of TET2 expression between resection #1 and #2 was correlated with relapse time (p=0.0377) (Figure 3B).

**Figure 3** The TET2 expression level correlates with a short relapse time in recurrent GBM.

### Discussion

Glioblastoma multiforme (GBM) is the most common and aggressive primary brain cancer. Despite the gain of survival associated with the use of a standard of care treatment composed by a maximal safe surgery followed by adjuvant chemoradiotherapy and adjuvant chemotherapy, recurrence is an inevitable event. Besides, literature reports that GBM patients underwent repeat resections with a median time between resections of 6-9 months [21,22]. On contrary to the first line of treatment, the treatment of recurrent GBMs (rGBMs) poses a great challenge since no well-defined recommendation of therapy is suggested. This point finds its echo in the multiples clinical trials performed about the rGBM treatment and with a large panel of drugs including: PARP inhibitor (Veliparnib, ClinicalTrials.
TET2 mutations and not on the TET2 expression level could be investigated to identify the role of TET2 inhibitors of the epidrug pipeline [24,25]. The focus on TET2 overexpression a consequence of the GBM recurrence?...

In conclusion, our data and the current lack of selectivity of TET2 inhibitors support the research for a better understanding of the role played by TET2 in GBM and for the design/development of highly selective TET2 inhibitors.

Declaration

Acknowledgements

JB was supported by a fellowship from EpiSVMEN/REGION PAYS DE LA LOIRE and “EN AVANT LA VIE”, a French association that fights against glioma. We thank to Dr P Menei and G Soulard for coordinating the patient sample procurement from BCB-G.

Funding

This work was supported by grants from the LIGUE NATIONALE CONTRE LE CANCER, “Comité InterRégional Grand Ouest, département de Loire-Atlantique, Vendée et Morbihan (AO2015/ Subvention2016)”.

Authors’ Contributions

PFC designed and coordinated the project.

JB, AN and PFC performed all experiments.

FMV and PFC interpreted and discussed the data.

PFC wrote the first version of the manuscript and all authors reviewed and approved it.

Conflicting Interests

The authors declare that they have no conflicting interests.
