## Abstract

During B cell development, the precursor B cell receptor (pre-BCR) checkpoint is thought to increase immunoglobulin  $\kappa$  light chain (*Ig $\kappa$* ) locus accessibility to the V(D)J recombinase. Accordingly, pre-B cells lacking the pre-BCR signaling molecules Btk or Slp65 showed reduced germline  $V_{\kappa}$  transcription. To investigate whether pre-BCR signaling modulates  $V_{\kappa}$  accessibility through enhancer-mediated *Ig $\kappa$*  locus topology, we performed chromosome conformation capture and sequencing analyses. These revealed that already in pro-B cells the  $\kappa$  enhancers robustly interact with the  $\sim 3.2$  Mb  $V_{\kappa}$  region and its flanking sequences. Analyses in wild-type, Btk, and Slp65 single- and double-deficient pre-B cells demonstrated that pre-BCR signaling reduces interactions of both enhancers with *Ig $\kappa$*  locus flanking sequences and increases interactions of the 3'  $\kappa$  enhancer with  $V_{\kappa}$  genes. Remarkably, pre-BCR signaling does not significantly affect interactions between the intronic enhancer and  $V_{\kappa}$  genes, which are already robust in pro-B cells. Both enhancers interact most frequently with highly used  $V_{\kappa}$  genes, which are often marked by transcription factor E2a. We conclude that the  $\kappa$  enhancers interact with the  $V_{\kappa}$  region already in pro-B cells and that pre-BCR signaling induces accessibility through a functional redistribution of long-range chromatin interactions within the  $V_{\kappa}$  region, whereby the two enhancers play distinct roles.

## Introduction

B lymphocyte development is characterized by stepwise recombination of immunoglobulin (Ig), variable (V), diversity (D), and joining (J) genes, whereby in pro-B cells the Ig heavy (H) chain locus rearranges before the *Ig $\kappa$*  or *Ig $\lambda$*  light (L) chain loci [1,2]. Productive *IgH* chain rearrangement is monitored by deposition of the *IgH*  $\mu$  chain protein on the cell surface, together with the preexisting surrogate light chain (SLC) proteins  $\lambda 5$  and VpreB, as the pre-B cell receptor (pre-BCR) complex [3]. Pre-BCR expression serves as a checkpoint that monitors for functional *IgH* chain rearrangement, triggers proliferative expansion, and induces developmental progression of large cycling into small resting Ig  $\mu^+$  pre-B cells in which the recombination machinery is reactivated for rearrangement of the *Ig $\kappa$*  or *Ig $\lambda$*  L chain loci [3,4].

During the V(D)J recombination process, the spatial organization of large antigen receptor loci is actively remodeled [5]. Overall locus contraction is achieved through long-range chromatin interactions between proximal and distal regions within these loci. This process brings distal V genes in close proximity to (D)J regions, to which Rag (recombination activating gene) protein binding occurs [6] and the nearby regulatory elements that are required for topological organization and recombination [5,7,8]. The recombination-associated changes in locus topology thereby provide equal opportunities for individual V genes to be recombined to a (D)J segment. Accessibility and recombination of antigen receptor loci are controlled by many DNA-binding factors that interact with local *cis*-regulatory elements, such as promoters, enhancers, or silencers [7–9]. The long-range chromatin interactions involved in this process are thought to be crucial for the regulation of V(D)J recombination and orchestrate

## Author Summary

B lymphocyte development involves the generation of a functional antigen receptor, comprising two heavy chains and two light chains arranged in a characteristic “Y” shape. To do this, the receptor genes must first be assembled by ordered genomic recombination events, starting with the immunoglobulin heavy chain (IgH) gene segments. On successful rearrangement, the resulting IgH  $\mu$  protein is presented on the cell surface as part of a preliminary version of the B cell receptor—the “pre-BCR.” Pre-BCR signaling then redirects recombination activity to the immunoglobulin  $\kappa$  light chain gene. The activity of two regulatory  $\kappa$  enhancer elements is known to be crucial for opening up the gene, but it remains largely unknown how the hundred or so Variable (V) segments in the  $\kappa$  locus gain access to the recombination system. Here, we studied a panel of pre-B cells from mice lacking specific signaling molecules, reflecting absent, partial, or complete pre-BCR signaling. We identify gene regulatory changes that are dependent on pre-BCR signaling and occur via long-range chromatin interactions between the  $\kappa$  enhancers and the V segments. Surprisingly the light chain gene initially contracts, but the interactions then become more functionally redistributed when pre-BCR signaling occurs. Interestingly, we find that the two enhancers play distinct roles in the process of coordinating chromatin interactions towards the V segments. Our study combines chromatin conformation techniques with data on transcription factor binding to gain unique insights into the functional role of chromatin dynamics.

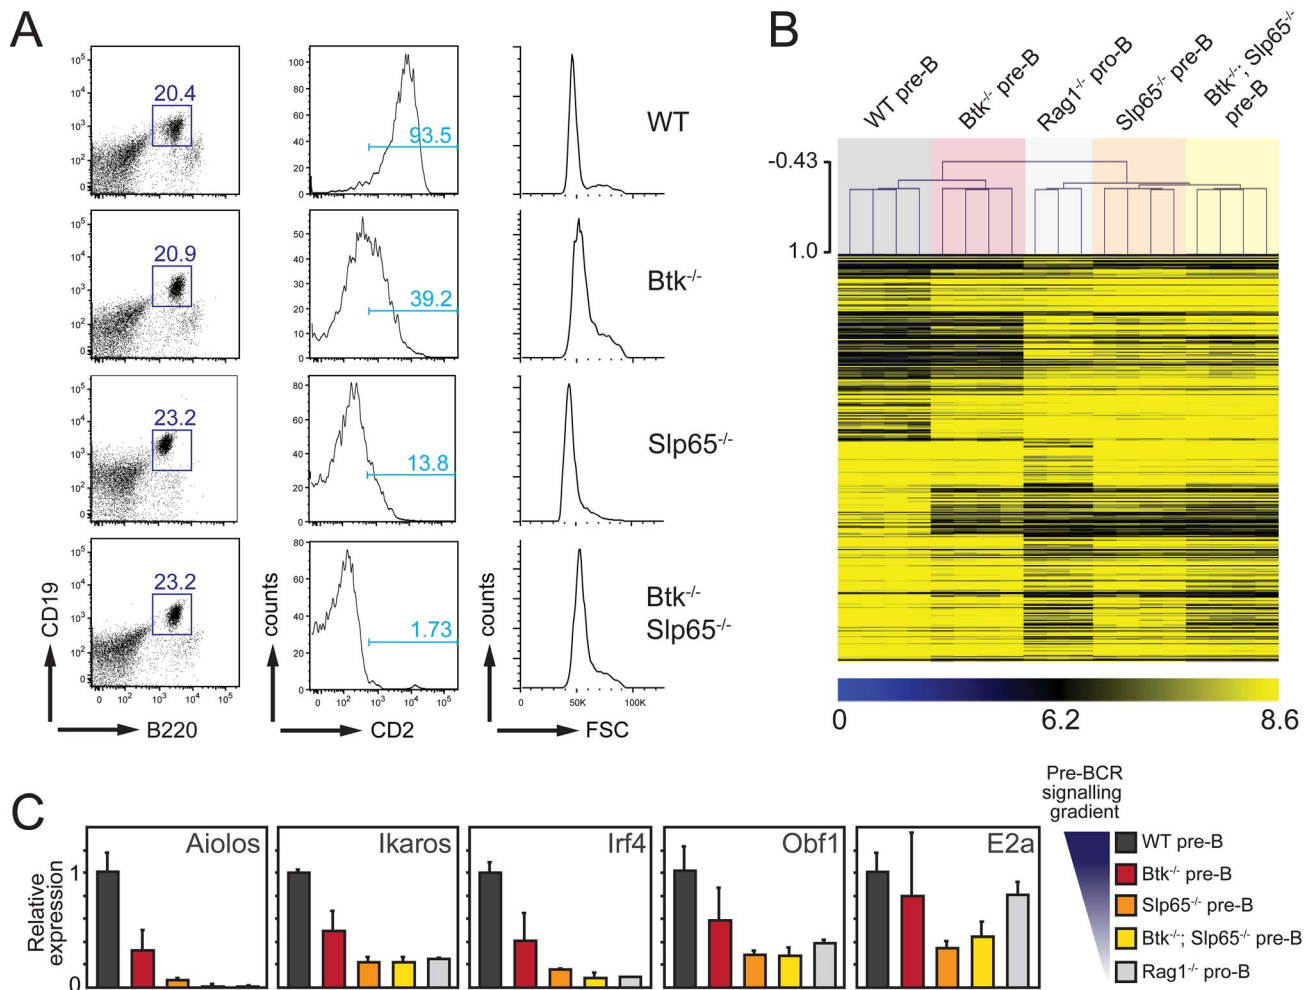

changes in subnuclear relocation, germline transcription, histone acetylation and/or methylation, DNA demethylation, and compaction of antigen receptor loci [5,10].

The mouse *Igk* locus harbors 101 functional  $V_{\kappa}$  genes and four functional  $J_{\kappa}$  elements and is spread over >3 Mb of genomic DNA [11]. Mechanisms regulating the site-specific DNA recombination reactions that create a diverse *Igk* repertoire are complex and involve local differences in the accessibility of the  $V_{\kappa}$  and  $J_{\kappa}$  genes to the recombinase proteins [12]. Developmental-stage-specific changes in gene accessibility are reflected by germline transcription, which precedes or accompanies gene recombination [13]. In the *Igk* locus, germline transcription is initiated from promoters located upstream of  $J_{\kappa}$  (referred to as  $\kappa^0$  transcripts) and from  $V_{\kappa}$  promoters [14]. Deletion of the intronic enhancer (iE $\kappa$ ), located between  $J_{\kappa}$  and  $C_{\kappa}$ , or the downstream 3' $\kappa$  enhancer (3'E $\kappa$ ), both containing binding sites for the E2a and Irf4/Irf8 transcription factors (TFs), diminishes *Igk* locus germline transcription and recombination [15–19]. On the other hand, the Sis (silencer in intervening sequence) element in the  $V_{\kappa}$ – $J_{\kappa}$  region negatively regulates *Igk* rearrangement [20]. This Sis element was shown to target *Igk* alleles to centromeric heterochromatin and to associate with the Ikaros repressor protein that also colocalizes with centromeric heterochromatin. Sis contains a strong binding site for the zinc-finger transcription regulator CTCF-binding factor (Ctcf) [21,22]. Interestingly, deletion of the Sis element or conditional deletion of the *Ctcf* gene in the B cell lineage both resulted in reduced  $\kappa^0$  germline transcription and enhanced proximal  $V_{\kappa}$  usage [21,23]. Very recently, a novel Ctcf binding element located directly upstream of the Sis region was shown to be essential for locus contraction and recombination to distal  $V_{\kappa}$  genes [23]. In addition, the *Igk* repertoire is controlled by the polycomb group protein YY1 [24].

Induction of *Igk* rearrangements requires the expression of the Rag1 and Rag2 proteins, the attenuation of the cell cycle, and transcriptional activation of the *Igk* locus, all of which are thought to be crucially dependent on pre-BCR signaling [4,25]. At first, pre-BCR signals synergize with interleukin-7 receptor (IL-7R) signals to drive proliferative expansion of IgH  $\mu^+$  large pre-B cells [4]. In these cells, transcription of the *Rag* genes is low and the Rag2 protein is unstable due to cell-cycle-dependent degradation [26]. Subsequently, signaling through the pre-BCR downstream adapter Slp65 (SH2-domain-containing leukocyte protein of 65 kDa, also known as Blnk or Bash) switches cell fate from proliferation to differentiation [4]. Importantly, Slp65 (i) induces the TF Aiolos, which down-regulates  $\lambda 5$  expression [27]; (ii) binds Jak3 and thereby interferes with IL-7R signaling [28]; and (iii) reduces inhibitory phosphorylation of Foxo TFs [29]. All these changes result in attenuation of the cell cycle and thus Rag protein stabilization. Moreover, *Rag* gene transcription is induced by Foxo proteins [30].

Although rearrangement and expression of the *Igk* locus can occur independently of IgH  $\mu$  chain expression [31,32], several lines of evidence indicate that pre-BCR signaling is actively involved in inducing *Igk* and *Igl* locus accessibility and gene rearrangement. First, surface IgH  $\mu$  chain expression correlates with germline transcription in the *Igk* locus [33]. Second, in the absence of Slp65,  $\kappa^0$  germline transcription is reduced [34]. Third, mice deficient for Bruton's tyrosine kinase (Btk), which is a pre-BCR downstream signaling molecule interacting with Slp65, show reduced *Igl* L chain germline transcription and reduced Ig $\lambda$  usage [35]. Fourth, transgenic expression of the constitutively active E41K-Btk mutant in IgH  $\mu$  chain negative pro-B cells induces premature rearrangement and protein expression of Ig $\kappa$  L chain [34]. Based on fluorescence in situ hybridization (FISH) studies, it has been proposed that in pro-B cells distal  $V_{\kappa}$  and  $C_{\kappa}$  genes are separated by large distances and that the *Igk* locus specifically undergoes contraction in small pre-B and immature B cells actively undergoing  $V_{\kappa}$ – $J_{\kappa}$  recombination [36]. However, it remains unknown how pre-BCR-induced signals affect the accessibility, contraction, and topology of the  $V_{\kappa}$  region, or how they affect the long-range interactions of the  $\kappa$  regulatory elements involved in organizing these events.

In this study, we identified the effects of pre-BCR signaling on germline  $V_{\kappa}$  transcription and on the expression of TFs implicated in the regulation of *Igk* gene rearrangement. We found that the decrease in pre-BCR signaling capacity in wild-type, Btk-deficient, Slp65-deficient, and Btk/Slp65 double-deficient pre-B cells was paralleled by a gradient of decreased expression of many TFs including Ikaros, Aiolos, Irf4, and (to a lesser extent) E2a, as well as by a decreased *Igk* locus accessibility for recombination. Several of these factors can mediate long-range chromatin interactions and are known to occupy  $\kappa$  regulatory elements that regulate locus accessibility [37–40]. We therefore sought to analyze the effect of pre-BCR signaling on the higher order chromatin structure organized by these regulatory sequences at the *Igk* locus. To this end, we performed chromosome conformation capture and sequencing (3C-seq) analyses [41] on pro-B cells and pre-B cells from mice single or double deficient for Btk or Slp65 to evaluate the effects of this pre-BCR signaling gradient on *Igk* locus topology. These 3C-seq experiments demonstrated that already in pro-B cells the  $\kappa$  enhancers robustly interact with the ~3.2 Mb  $V_{\kappa}$  region and its flanking sequences, and that pre-BCR signaling induces accessibility by a functional redistribution of enhancer-mediated chromatin interactions within the  $V_{\kappa}$  region.

**Figure 1. Gene expression profiling strategy for the identification of genes regulated by Btk/Slp65-mediated pre-BCR signaling.** (A) FACS sorting strategy for purification of pre-B cell fractions from the indicated mice on a VH81x transgenic *Rag1*<sup>-/-</sup> background. Lymphocytes were gated on the basis of forward/side scatter and B220<sup>+</sup>CD19<sup>+</sup> pre-B cell fractions were sorted. Virtually all B220<sup>+</sup>CD19<sup>+</sup> cells were cytoplasmic  $\mu$  heavy chain positive [34], but showed genotype-dependent levels of expression of the CD2 differentiation marker, in agreement with previous findings [34]. (B) DNA microarray analysis of total mRNA from FACS-purified B220<sup>+</sup>CD19<sup>+</sup> pre-B/pro-B cell fractions from the indicated mice. One-way ANOVA analysis ( $p=0.01$ ) identified 266 significantly different genes. MeV hierarchical clustering of gene expression differences are represented in the heatmap. (C) Validation of the expression of TFs implicated in *Igκ* gene rearrangement. Total mRNA isolated from FACS-sorted B220<sup>+</sup>CD19<sup>+</sup> pre-B/pro-B cell fractions from the indicated mice was analyzed by quantitative RT-PCR for expression of TFs. Expression levels were normalized to those of *Gapdh*, whereby the values in WT pre-B cells were set to one. Bars represent mean values and error bars denote standard deviations for four independent mice per group.

## Results

### Identification of Genes Regulated by Pre-BCR Signaling

Whereas mice deficient for the pre-BCR signaling molecules Btk and Slp65 have a partial block at the pre-B cell stage [42,43], in Btk/Slp65 double-deficient mice, only very few pre-B cells show progression to the immature B cell stage characterized by functional *IgL* chain gene recombination [44]. To enable analysis of the effects of pre-BCR signaling on (i) the expression of genes involved in *Igκ* gene rearrangement and on (ii) long-distance chromatin interactions in the *Igκ* locus in pre-B cells in the absence of *Igκ* gene recombination events, we bred Btk and Slp65 single- and double-deficient mice on the *Rag1*<sup>-/-</sup> background. In these mice, progression of B cell progenitors to the pre-B cell stage was conferred by the transgenic, functionally rearranged VH81x IgH  $\mu$  chain, which ensures pre-BCR expression and cellular proliferation.

The absence of functional Rag1 protein precludes *IgL* chain gene rearrangement and cells are completely arrested at the small pre-B cell stage (Figure 1A).

We performed genome-wide expression profiling of FACS-purified B220<sup>+</sup>CD19<sup>+</sup> pre-B cell fractions from wild-type (WT), Btk, and Slp65 single- and double-deficient VH81x transgenic *Rag1*<sup>-/-</sup> mice (Figure 1A). In these experiments non-VH81x transgenic *Rag1*<sup>-/-</sup> pro-B cells served as controls. One-way ANOVA analysis using MeV software ( $p<0.01$ ) [45] revealed that 266 genes were differentially expressed between the five groups of pro-B/pre-B cells (Figure 1B). When compared with WT VH81x transgenic *Rag1*<sup>-/-</sup> pre-B cells, 174 genes were up-regulated, whereby the average values of the fold increase were  $\sim 1.70$ ,  $\sim 3.28$ ,  $\sim 3.36$ , and  $\sim 3.47$  for Btk<sup>-/-</sup>, Slp65<sup>-/-</sup>, Btk<sup>-/-</sup>Slp65<sup>-/-</sup> VH81x transgenic *Rag1*<sup>-/-</sup> pre-B cells and non-VH81x transgenic *Rag1*<sup>-/-</sup> pro-B cells, respectively (see Table S1). A similar gradient of gene expression

changes was apparent from the average values of the fold change for the 192 significantly down-regulated genes, which were  $\sim 1.65$ ,  $\sim 2.29$ ,  $\sim 3.79$ , and  $\sim 4.15$  in the four groups of pre-B/pro-B cells, respectively (see Table S2). In a hierarchical clustering analysis of the five groups of B cell precursors, the expression profiles of *Btk*<sup>-/-</sup> *Slp65*<sup>-/-</sup> VH81x transgenic *Rag1*<sup>-/-</sup> pre-B cells and non-VH81x transgenic *Rag1*<sup>-/-</sup> pro-B cells were very similar (Figure 1B). This implies that expression of the 266 genes is not substantially influenced by pre-BCR-mediated proliferation, which is still induced in pre-B cells lacking both *Btk* and *Slp65* [44,46] but not in *Rag1*<sup>-/-</sup> pro-B cells. Consistent with these findings, gene distance matrix analysis revealed a clear gene expression gradient among the five groups of pre-B/pro-B cells, in which *Btk*<sup>-/-</sup> *Slp65*<sup>-/-</sup> pre-B and *Rag1*<sup>-/-</sup> pro-B cells again showed highly comparably expression signatures (Figure S1).

In agreement with previous findings [34,43,46], pre-BCR signaling-defective pre-B cells manifested increased expression of *Dnmt*, encoding terminal deoxynucleotidyl transferase and the SLC components *Vpre* (*Vpreb1*) and  $\lambda 5$  (*Igll1*), as well as decreased expression of the cell surface markers *Cd2*, *Cd22*, *Cd25* (IL-2R), and MHC class II (Table 1). *Btk* and *Slp65* single-deficient and particularly double-deficient pre-B cells failed to up-regulate various genes known to be involved in *Ig*L chain recombination, such as *Ikzf3* (Aiolos), *Ikzf1* (Ikaros), *Irf4*, *Spib*, *Pou2f2* (Oct2), polymerase- $\mu$  [47], as well as *Hivep1* encoding the Mbp-1 protein, which has been shown to bind to the  $\kappa$  enhancers [48]. In addition, pre-BCR signaling influenced the expression levels of many other DNA-binding or modifying factors that were not previously associated with *Ig*L chain recombination, including *Lmo4*, *Zfp710*, *Arid1a/3a/3b*, the lysine-specific demethylases *Aof1* and *Plzf2*, *Prdm2* (a H3K9 methyltransferase), the *sik1* gene encoding a histone deacetylase (HDAC) kinase, *Hdac5*, *Hdac8*, and the DNA repair protein gene *Rev1* (Table S2). We did not find significant differences in the expression of several other TFs implicated in Ig gene recombination—for example, *Obf1/Oca-B*, *Pax5*, *E2a*, and *Irf8* (Table 1). In addition, in signaling-deficient pre-B cells, we found reduced transcription of genes encoding several signaling molecules (e.g., *Rasgrp1*, *Rapgef11*, *Ralgs2*, *Blk*, *Traf5*, *Hck*, *Nfkb1a* (IkB $\alpha$ ), *Syk*, *Csk*), cell surface markers (*Cd38*, *Cd72*, *Cd74*, *Cd55*, and *Notch2*), or genes regulating cell survival (*Bmf* and *Bcl2l1* encoding Bcl<sub>X</sub>L) (Table S2). Interestingly, we observed concomitant up-regulation of signaling molecules that are also associated with the T cell receptor (*Lat*, *Zap70*, and *Prkcg* (PKC $\theta$ ); Table S1).

Next, we used quantitative RT-PCR to confirm the observed differential expression of several TFs. Expression levels of these genes were indeed significantly reduced in a pre-BCR signaling-dependent manner, especially for Aiolos, Ikaros, and *Irf4*, with residual expression levels in *Btk*<sup>-/-</sup> *Slp65*<sup>-/-</sup> VH81x transgenic *Rag1*<sup>-/-</sup> pre-B cells that were  $\sim 1\%$ ,  $\sim 20\%$ , and  $\sim 9\%$  of those observed in WT VH81x *Rag1*<sup>-/-</sup> mice, respectively (Figure 1C). In addition, we found moderate effects on *Obf1* (Oca-B) and *E2a* with residual expression levels of  $\sim 28\%$  and  $\sim 44\%$ , respectively. In chromatin immunoprecipitation (ChIP) assays, we observed in pre-B cells substantial binding of E2a protein to the intronic and 3'  $\kappa$  enhancer regions and to the three  $V_{\kappa}$  regions analyzed. Under conditions of reduced pre-BCR signaling activity, E2a binding to the enhancers was essentially maintained (3'E $\kappa$ ) or reduced (iE $\kappa$ ), but E2a binding to the  $V_{\kappa}$  regions was lost (Table S3). Consistent with the significant reduction of Ikaros expression in *Slp65*<sup>-/-</sup> pre-B cells, Ikaros binding to both  $\kappa$  enhancers and  $V_{\kappa}$  regions was undetectable in these cells (Table S3).

Taken together, from these findings we conclude that the five groups of pro-B/pre-B cells, representing a gradient of

progressively diminished pre-BCR signaling, show in parallel a gradient of diminished modulation of many genes that signify pre-B cell differentiation, including key genes implicated in *Ig* $\kappa$  gene recombination.

### Progressively Diminished $V_{\kappa}$ and $J_{\kappa}$ GLTs in *Btk*<sup>-/-</sup>, *Slp65*<sup>-/-</sup>, and *Btk*<sup>-/-</sup> *Slp65*<sup>-/-</sup> Pre-B Cells

In these expression profiling studies, we only detected limited differences in germline transcription (GLT) over unrearranged  $J_{\kappa}$  and  $V_{\kappa}$  gene segments, which is thought to reflect locus accessibility [12]. However, we previously showed by serial-dilution RT-PCR that the levels of  $\kappa^0$  0.8 and  $\kappa^0$  1.1 germline transcripts, which are initiated in different regions 5' of  $J_{\kappa}$  and spliced to the  $C_{\kappa}$  region [49], are apparently normal in *Btk*<sup>-/-</sup> pre-B cells, modestly reduced in *Slp65*<sup>-/-</sup> pre-B cells, and severely reduced in *Btk*<sup>-/-</sup> *Slp65*<sup>-/-</sup> pre-B cells [34]. We could confirm these findings for  $\kappa^0$  GLT by quantitative RT-PCR assays on FACS-purified B220<sup>+</sup>CD19<sup>+</sup> pro-B/pre-B cell fractions (Figure 2A). In agreement with our reported findings [34], we also found that *Btk*<sup>-/-</sup> and *Slp65*<sup>-/-</sup> pre-B cells have defective  $\lambda^0$  transcription, which is initiated 5' of the  $J_{\lambda}$  segments (Figure 2B) [49].

GLT across the  $V_{\kappa}$  region showed a similar pattern of sensitivity to pre-BCR signaling: decreased transcription of six individual  $V_{\kappa}$  regions tested ( $V_{\kappa}3-7$ ,  $V_{\kappa}8-24$ ,  $V_{\kappa}4-55$ ,  $V_{\kappa}10-96$ ,  $V_{\kappa}1-35$ , and  $V_{\kappa}2-137$ ) correlated with decreased pre-BCR signaling activity (Figure 2C) in the pre-B cells of the four groups of mice. GLT over unrearranged  $V_{\lambda}1$  and  $V_{\lambda}2$  segments was strongly reduced in the absence of *Btk* or *Slp65*, as detected by the expression arrays (Table 1).

These observations indicate that *Ig* $\kappa$  locus accessibility, a hallmark of recombination-competent antigen receptor loci, is progressively reduced under conditions of diminishing pre-BCR signaling.

### Pre-BCR Signaling Induces Modulation of Long-Range Chromatin Interactions at the *Ig* $\kappa$ Locus

Accessibility of antigen receptor loci for V(D)J recombination is thought to be initiated by enhancers, in part through long-range chromatin interactions with promoters of noncoding transcription, resulting in the activation of germline transcription [8]. Because pre-BCR signaling affects the expression of GLT and various nuclear proteins that mediate long-range chromatin interactions and bind the  $\kappa$  enhancers, it is conceivable that pre-BCR signaling induces changes in the enhancer-mediated higher order chromatin structure of the *Ig* $\kappa$  locus that facilitates  $V_{\kappa}$  gene accessibility.

We therefore performed 3C-Seq analyses on FACS-purified B220<sup>+</sup>CD19<sup>+</sup> fractions from the same five groups of mice (WT, *Btk*<sup>-/-</sup>, *Slp65*<sup>-/-</sup>, and *Btk*<sup>-/-</sup> *Slp65*<sup>-/-</sup> VH81x transgenic *Rag1*<sup>-/-</sup> pre-B cells, as well as *Rag1*<sup>-/-</sup> pro-B cells). Erythroid progenitors were analyzed in parallel as a nonlymphoid control, in which the *Ig* $\kappa$  locus was not contracted. Genome-wide chromatin interactions were measured for three regulatory elements involved in the control of *Ig* $\kappa$  locus accessibility and recombination: the iE $\kappa$  and 3'E $\kappa$  enhancers [50–52] and the *Sis* element [20], which contain binding sites for Ikaros/Aiolos, E2a, and *Irf4* [16,17,20,38,53].

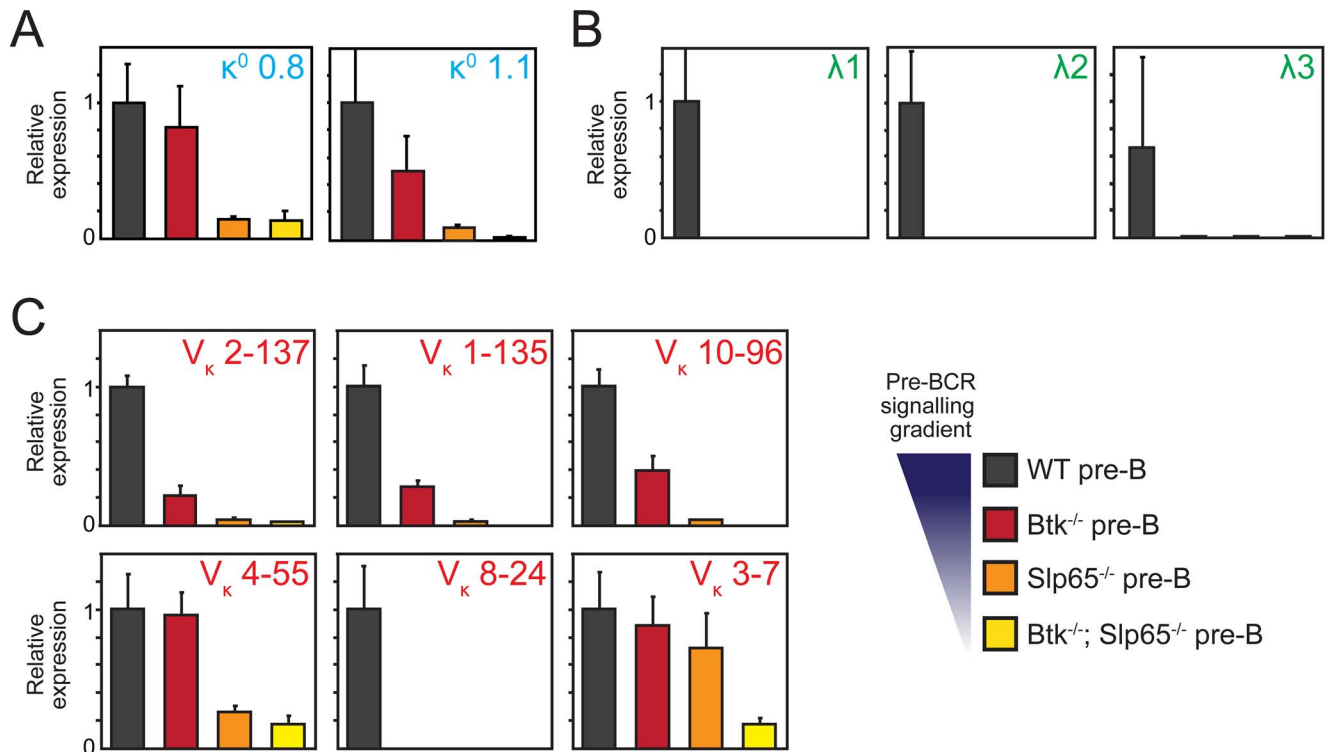

In WT pre-B cells, all three regulatory elements showed extensive long-range chromatin interactions within the  $V_{\kappa}$  region and substantially less interactions with regions up- or downstream of the  $\sim 3.2$  Mb *Ig* $\kappa$  domain (Figure 3A; see Figure S2, Figure S3, and Figure S4 for line graphs), confirming previous observations [21]. Under conditions of reduced pre-BCR signaling activity, the three *Ig* $\kappa$  regulatory elements still showed strong interactions with

**Figure 2. Reduction of Btk/Slp65-mediated pre-BCR signaling is associated with progressive loss of Ig $\kappa$  GLT.** Quantitative RT-PCR analysis for  $\kappa^0$  (A),  $\lambda^0$  (B), and  $V_\kappa$  GLT (C) of FACS-sorted B220<sup>+</sup>CD19<sup>+</sup> pre-B/pro-B cell fractions from the indicated mice on a VH81x transgenic *Rag1*<sup>-/-</sup> background. Expression levels were normalized to those of *Gapdh*, whereby the values in WT pre-B cells were set to one. Bars represent mean values and error bars denote standard deviations for four independent mice per group. doi:10.1371/journal.pbio.1001791.g002

the  $V_\kappa$  region. Surprisingly, even in the complete absence of pre-BCR signaling in *Rag1*<sup>-/-</sup> pro-B cells, long-range interactions were still observed at frequencies well above those seen in nonlymphoid cells, suggesting that a contracted *Igk* locus topology is not strictly dependent on pre-BCR signaling (Figure 3A, Figure S2, Figure S3, and Figure S4). Next, we used 3D DNA FISH analyses using BAC probes hybridizing to the distal  $V_\kappa$  and  $C_\kappa$ /enhancer regions to confirm that *Igk* locus contraction was similar in *Rag1*<sup>-/-</sup> pro-B cells and VH81x transgenic *Rag1*<sup>-/-</sup> pre-B cells (both showing a contracted topology, compared with noncontracted pre-pro-B cells deficient for the TF E2a; Figure 3B).

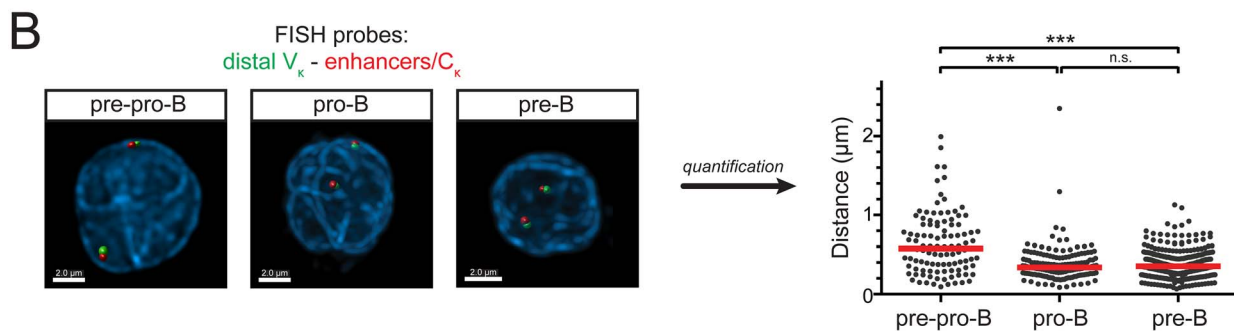

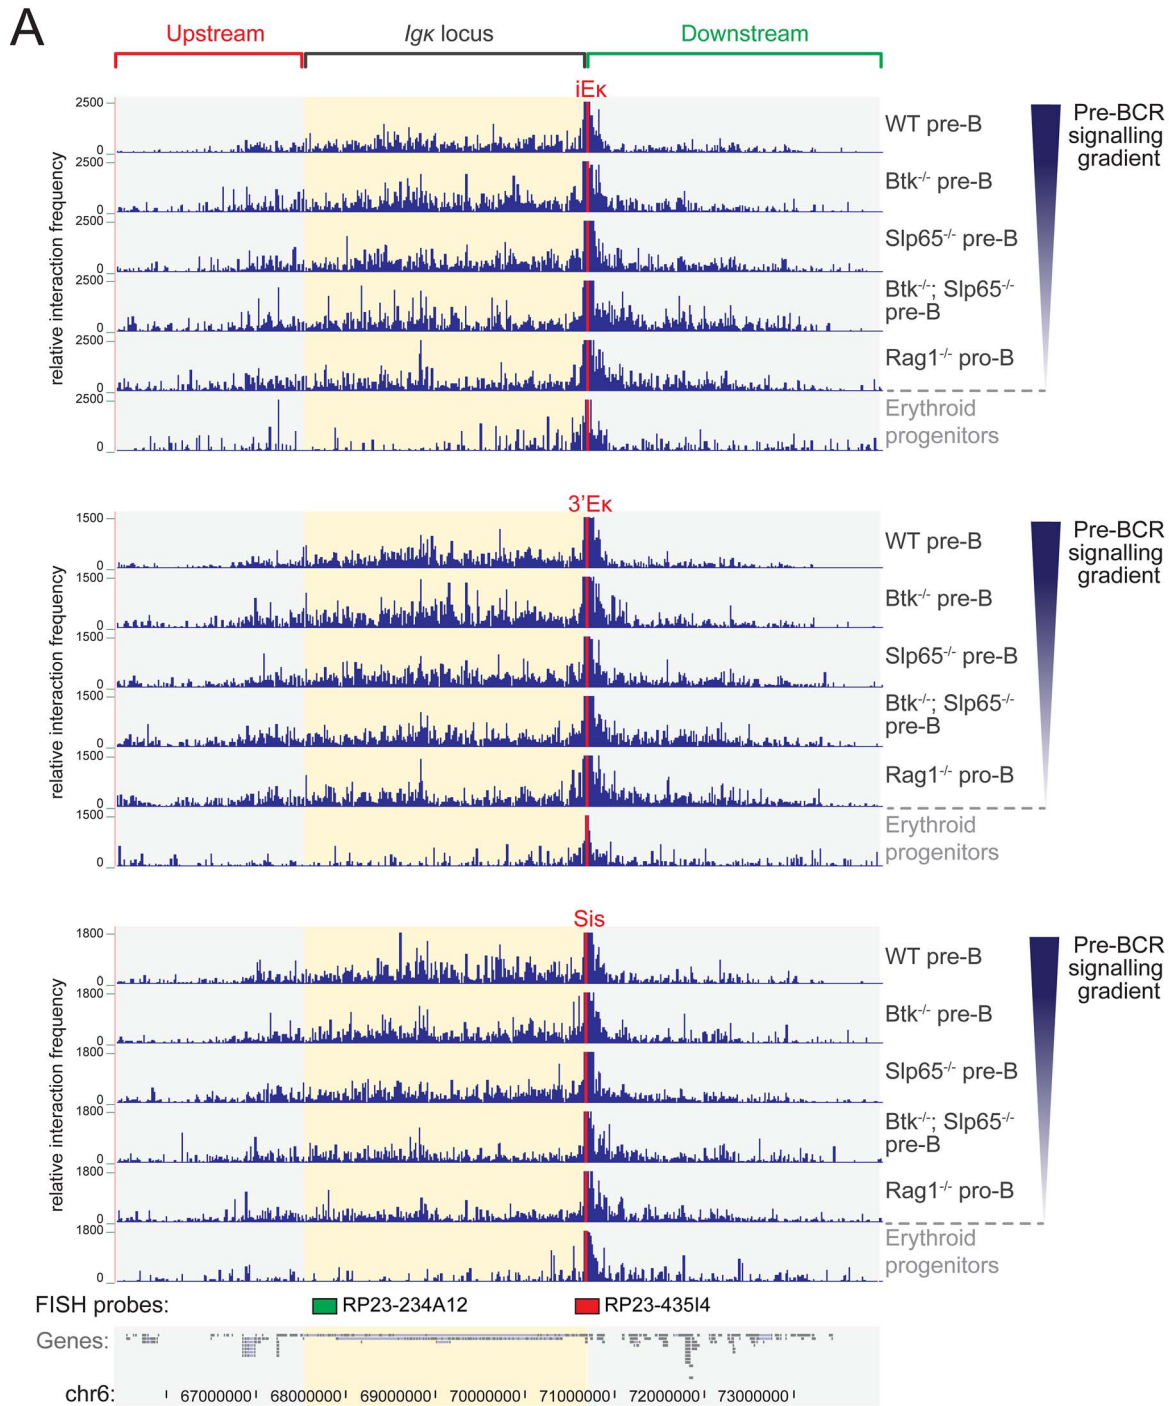

Nevertheless, we did observe that pre-BCR signaling induced clear differences in interaction frequencies. Whereas an increase in pre-BCR signaling was associated with a decrease in the interaction frequencies between the two  $\kappa$  enhancers and regions flanking the *Igk* locus (as also revealed by more detailed images of selected regions upstream and downstream of the *Igk* domain; see Figure S5), the overall interaction frequency within the *Igk* domain appeared unchanged (Figure S3, Figure S4, and Figure S5). Remarkably, interactions with the Sis element showed quite an opposite pattern: pre-BCR signaling correlated with increased overall interactions within the *Igk* domain and did not substantially affect interaction frequencies in the *Igk* flanking regions (Figure S2 and Figure S5).

Taken together, these analyses show that (i) the *Igk* locus is already contracted at the pro-B cell stage and that (ii) pre-BCR signaling induces changes in long-range chromatin interactions, both within the *Igk* locus and in the flanking regions.

### Pre-BCR Signaling Enhances Interactions of 3'E $\kappa$ and Sis, But Not iE $\kappa$ , with $V_\kappa$ <sup>+</sup> Fragments

The differential effects of pre-BCR signaling on long-range chromatin interactions of the iE $\kappa$ , 3'E $\kappa$ , and Sis elements clearly emerged in a quantitative analysis of the 3C-seq datasets (Figure 4A; see Materials and Methods for a detailed description of the quantification methods used). When pre-BCR signaling was absent (*Rag1*<sup>-/-</sup> pro-B cells) or very low (*Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cells), the average interaction frequencies were similar within the ~3.2 Mb  $V_\kappa$  region and the ~3.2 Mb downstream flanking region, for all three regulatory elements. Interaction frequencies with the upstream flanking region were lower, consistent with the larger chromosomal distance to the three viewpoints. The presence of increasing levels of Btk/Slp65-mediated pre-BCR signaling was associated with reduced interaction of iE $\kappa$  and 3'E $\kappa$  with the *Igk* flanking regions and with increased interaction of the Sis element and (to a lesser extent) 3'E $\kappa$  with the  $V_\kappa$  region (Figure 4A). As a result, for all three regulatory elements pre-BCR signaling resulted in a preference for interaction with fragments inside the  $V_\kappa$  region over fragments outside the  $V_\kappa$  region (Figure S7).

We next focused our analysis on the  $V_\kappa$  region and compared fragments that harbor a functional  $V_\kappa$  gene ( $V_\kappa$ <sup>+</sup> fragment) and those that do not ( $V_\kappa$ <sup>-</sup> fragment). When pre-BCR signaling was absent (*Rag1*<sup>-/-</sup> pro-B cells) or very low (*Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cells), the average interaction frequencies of the Sis or iE $\kappa$  elements with  $V_\kappa$ <sup>+</sup> fragments were higher than with  $V_\kappa$ <sup>-</sup> fragments. The average interaction frequencies of 3'E $\kappa$  with  $V_\kappa$ <sup>+</sup> and  $V_\kappa$ <sup>-</sup> fragments, however, were similar (Figure 4B). Upon pre-BCR signaling, the Sis element showed an increase in interaction frequencies with both  $V_\kappa$ <sup>+</sup>

**Figure 3. 3C-Seq analysis of long-range chromatin interactions within the Ig $\kappa$  locus and flanking regions.** (A) Overview of long-range interactions revealed by 3C-Seq experiments performed on the indicated cell fractions, representing a gradient of pre-BCR signaling, whereby the iE $\kappa$  element (top), the 3'E $\kappa$  element (center), or the Sis element (bottom) was used as a viewpoint. Shown are the relative interaction frequencies (average of two replicate experiments) for the indicated genomic locations. The  $\sim 8.4$  Mb region containing the Ig $\kappa$  locus (yellow shading) and flanking regions (cyan shading) is shown and genes and genomic coordinates are given (bottom). The locations of the two BAC probes used for 3D DNA-FISH are indicated by a green (distal V $\kappa$  probe) and red (proximal C $\kappa$ /enhancer probe) rectangle (bottom). Pre-B cell fractions were FACS-purified from the indicated mice on a VH81x transgenic *Rag1*<sup>-/-</sup> background (see Figure 1 for gating strategy). Erythroid progenitor cells were used as a nonlymphoid control. (B) 3D DNA-FISH analysis comparing locus contraction in cultured bone-marrow-derived E2a<sup>-/-</sup> pre-pro-B, *Rag1*<sup>-/-</sup> pro-B, and VH81x *Rag1*<sup>-/-</sup> pre-B cells (see Figure S6 for phenotype of IL-7 cultured B-lineage cells). Locations of the BAC probes used are indicated at the bottom of panel A. Representative images for all three cell types are shown on the left, quantifications ( $>100$  nuclei counted per cell type) on the right. The red lines indicate the median distance between the two probes. Statistical significance was determined using a Mann-Whitney U test (\*\* $p < 0.001$ ; n.s., not significant,  $p \geq 0.05$ ). doi:10.1371/journal.pbio.1001791.g003

and V $\kappa$ <sup>-</sup> fragments, with nevertheless an interaction preference for V $\kappa$ <sup>+</sup> fragments. In contrast, interaction frequencies between the iE $\kappa$  element and V $\kappa$ <sup>+</sup> or V $\kappa$ <sup>-</sup> fragments were not modulated by pre-BCR signaling at all (Figure 4B). The 3'E $\kappa$  element exhibited yet another profile: pre-BCR signaling induced increased interaction frequencies specifically with V $\kappa$ <sup>+</sup> fragments, while interactions with V $\kappa$ <sup>-</sup> fragments were not notably modulated by pre-BCR signaling (Figure 4B). When we separately analyzed nonfunctional pseudo-V $\kappa$  genes, we found for the Sis and 3'E $\kappa$  elements that the interaction patterns with functional and nonfunctional V $\kappa$  genes were similar (Figure S8). In contrast, the iE $\kappa$  enhancer did show an overall increased interaction frequency with V $\kappa$  functional genes, compared with nonfunctional V $\kappa$  genes, a phenomenon which was again independent from pre-BCR signaling (Figure S8).

The finding that interactions of V $\kappa$  genes with the intronic enhancer are already robust in pro-B cells, while those with the 3' $\kappa$  enhancer are dependent on pre-BCR signaling, suggested that for individual V $\kappa$  genes pre-BCR signaling may result in more similar interaction frequencies with the two enhancers. To investigate this, we examined for all individual V $\kappa$  genes the correlation between their 3C-seq interaction frequencies with the iE $\kappa$  and 3' $\kappa$  elements and found that these were highly correlated in WT pre-B cells ( $R^2 = 0.68$ ; Figure 4C). Correlation was severely reduced when pre-BCR signaling was low in *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cells ( $R^2 = 0.26$ ; Figure 4C). Similar pre-BCR signaling-dependent correlations were observed between V $\kappa$ -interactions with the Sis element and those with the two enhancers (Figure S9). As the Sis element particularly suppresses recombination of the proximal V $\kappa$ 3 family, we investigated interaction correlations specifically for this V $\kappa$  family. Similar to our findings for all V $\kappa$  genes, a subanalysis showed strong correlations for the interactions of V $\kappa$ 3 family genes with iE $\kappa$ , 3' $\kappa$ , and Sis in WT pre-B cells, which were diminished when pre-BCR signaling was low, except for iE $\kappa$ -Sis correlations, which were pre-BCR signaling-independent (Figure S9).

In summary, we conclude that pre-BCR signaling induces a redistribution of long-range interactions of the iE $\kappa$ , 3'E $\kappa$ , and Sis elements, thereby restricting interactions towards the V $\kappa$  gene region. Moreover, upon pre-BCR signaling the long-range interactions mediated by 3'E $\kappa$  and Sis—but not those mediated by iE $\kappa$ —become enriched for fragments harboring a V $\kappa$  gene, demonstrating increased proximity of 3'E $\kappa$  and Sis to V $\kappa$  genes. Finally, for individual V $\kappa$  genes, the interactions with iE $\kappa$ , 3'E $\kappa$ , and Sis become highly correlated upon pre-BCR signaling, indicating that pre-BCR signals result in regulatory coordination between these three elements that govern Ig $\kappa$  locus recombination. In contrast, interactions between genes of the proximal V $\kappa$ 3 family, Sis and iE $\kappa$ —but not 3' $\kappa$ —appear to be coordinated already in the absence of pre-BCR signaling.

### Long-Range Chromatin Interactions of $\kappa$ Regulatory Elements Correlate with V $\kappa$ Usage

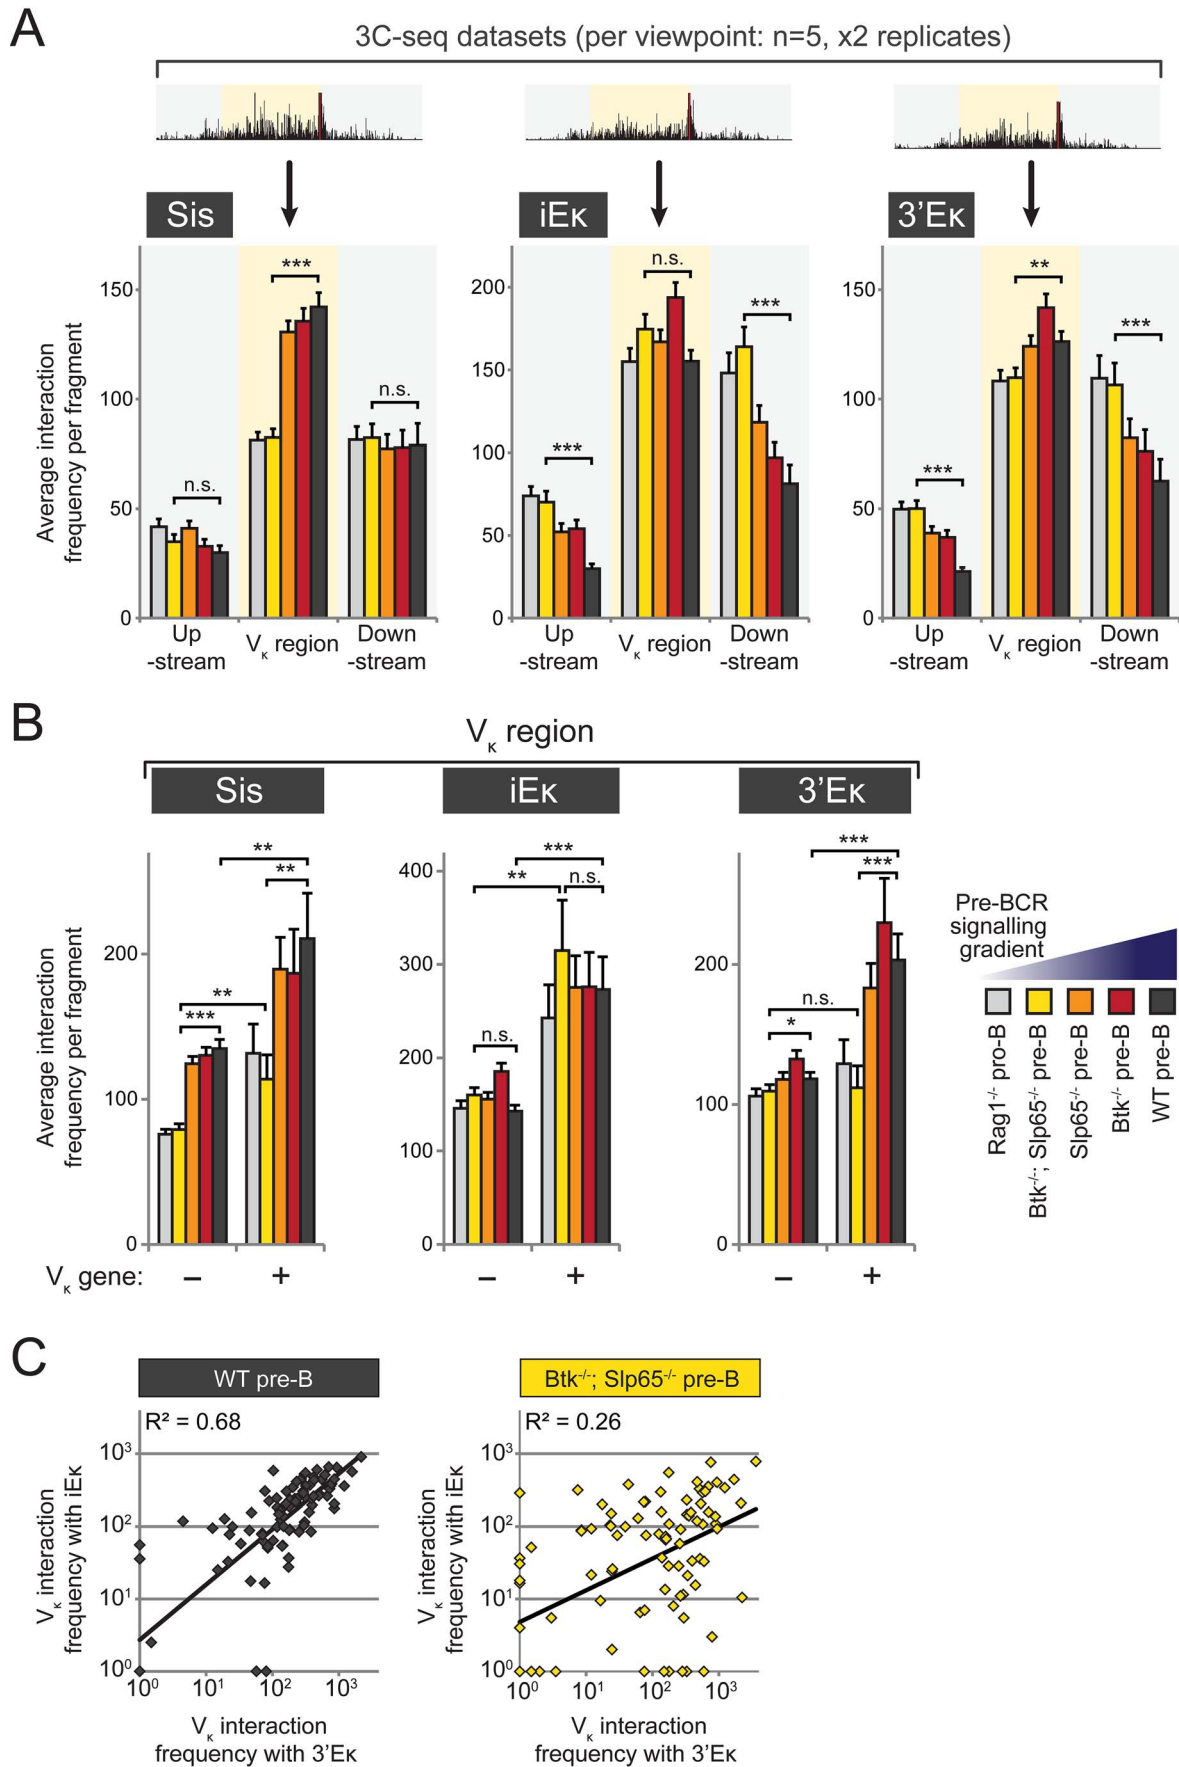

Next, we investigated the effects of pre-BCR signaling on the interaction frequencies of individual functional V $\kappa$  genes with the three  $\kappa$  regulatory elements (Figure 5A,B). The 3C-seq patterns of the majority ( $\sim 91\%$ ) of the 101 individual V $\kappa$ <sup>+</sup> fragments showed evidence for interaction with one or more of the  $\kappa$  regulatory elements ( $>25$  average counts). When comparing *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> with WT pre-B cells, we observed that for a large proportion ( $\sim 38$ – $52\%$ ) of V $\kappa$ <sup>+</sup> fragments, interaction frequencies increased upon pre-BCR signaling (Figure 5B). Smaller proportions of V $\kappa$ <sup>+</sup> fragments showed a decrease ( $\sim 12$ – $29\%$ ) or were not significantly affected by pre-BCR signaling ( $\sim 17$ – $25\%$  with  $<1.5$ -fold change). The observed increase or decrease was not related to proximal or distal location of the V $\kappa$  genes, nor to their sense or antisense orientation (not shown). Distributions of the three different classes of V $\kappa$ <sup>+</sup> fragments showed substantial differences between the  $\kappa$  regulatory elements. For the Sis and 3'E $\kappa$  elements, more V $\kappa$ <sup>+</sup> fragments showed increased than decreased interactions (Figure 5B), in agreement with the signaling-dependent increase in average interaction frequencies of all V $\kappa$ <sup>+</sup> fragments (Figure 4B). In contrast, for the iE $\kappa$  viewpoint, V $\kappa$ <sup>+</sup> fragments showing increased and decreased interactions were more equal in number, consistent with the limited effects of pre-BCR signaling on overall iE $\kappa$  interaction frequencies of all V $\kappa$ <sup>+</sup> fragments (Figure 4B).

Although antigen receptor recombination is in principle regarded as a random process, a significant skewing of the primary Ig $\kappa$  repertoire of C57BL/6 mice was recently reported: one third of the V $\kappa$  genes was shown to account for  $>85\%$  of the V $\kappa$  segments used by B cells [54]. To assess whether a correlation exists between usage of V $\kappa$  genes and their interaction frequencies with  $\kappa$  regulatory elements, we divided the V $\kappa$  genes into four usage categories ( $<0.1\%$ ,  $0.1$ – $0.3\%$ ,  $0.3$ – $0.5\%$ , and  $>0.5\%$ ) and calculated their average 3C-Seq interaction frequencies with Sis, iE $\kappa$ , and 3' $\kappa$  (Figure 5C). In WT pre-B cells, V $\kappa$  usage showed a strong positive correlation with 3C-Seq interaction frequencies for all three regulatory elements ( $R^2 = \sim 0.7$ – $0.9$ ; Figure 5C). These correlations were pre-BCR signaling-dependent, since in *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cells, they were reduced (for iE $\kappa$ ;  $R^2 = 0.33$ ) or absent (for Sis and 3' $\kappa$ ;  $R^2 < 0.10$  and  $R^2 < 0.16$ , respectively) (Figure 5C).

Collectively, our results indicate that specifically the most frequently used V $\kappa$  genes are the main interaction targets of  $\kappa$  regulatory elements, whereby pre-BCR signaling completely underlies this specificity for the Sis and 3'E $\kappa$  elements, and to a lesser extent for iE $\kappa$ .

### Long-Range Interactions with $\kappa$ Regulatory Elements Correlate with the Presence of Ctcf, Ikaros, E2a, and H3K4 Hypermethylation

Next, we investigated whether long-range interactions between  $\kappa$  regulatory elements and the V $\kappa$  region correlated with the presence of the TFs Ctcf [21], Ikaros [55], and E2a [56], which

**Figure 4. Modulation of long-range chromatin interactions within the Ig $\kappa$  locus by pre-BCR signaling.** Quantitative analysis of 3C-Seq datasets using the three indicated  $\kappa$  regulatory elements as viewpoints. (A) Average long-range chromatin interaction frequencies (from two replicate 3C-seq experiments) with upstream ( $\sim 2.0$  Mb),  $V_{\kappa}$  ( $\sim 3.2$  Mb), and downstream ( $\sim 3.2$  Mb) regions, as defined in Figure 3A, for the five B-cell precursor fractions representing a pre-BCR signaling gradient. Average interaction frequencies per region were calculated as the average number of 3C-Seq reads per restriction fragment within that region. See Materials and Methods section for more details. (B) Average interaction frequencies within the  $V_{\kappa}$  region were determined for fragments that do not (–) contain a functional  $V_{\kappa}$  gene and for those that do contain a functional  $V_{\kappa}$  gene (+). (C) Correlation plots of average interaction frequencies of the two enhancer elements with the 101 functional  $V_{\kappa}$  genes for WT pre-B cells (left) versus *Btk*<sup>–/–</sup>*Slp65*<sup>–/–</sup> pre-B cells (right). On the log scale, frequencies  $< 1$  were set to  $10^0$ . Statistical significance was determined using a Mann–Whitney U test (\* $p < 0.05$ ; \*\* $p < 0.01$ ; \*\*\* $p < 0.001$ ; n.s., not significant,  $p \geq 0.05$ ). doi:10.1371/journal.pbio.1001791.g004

have been implicated in *Igk* locus recombination [21,37,55,57,58]. Notably, Ikaros and E2a both strongly bind all three  $\kappa$  regulatory elements, while the *Sis* element is also occupied by Ctfc ([21]; unpublished data).

Remarkably, we found similar striking correlations between the presence of *in vivo* binding sites for each of these TFs (as determined by ChIP experiments; see Materials and Methods for the relevant references) and long-range chromatin interactions with the  $\kappa$  regulatory elements (Figure 6A–C), even though Ctfc sites are mostly located in between  $V_{\kappa}$  genes [21] and Ikaros/E2a sites were frequently found close to  $V_{\kappa}$  gene promoter regions ([2]; Figure 7A). Even when pre-BCR signaling was absent (*Rag1*<sup>–/–</sup> pro B cells) or very low (*Btk*<sup>–/–</sup>*Slp65*<sup>–/–</sup> pre-B cells), the average interaction frequencies of the  $\kappa$  regulatory elements with fragments containing Ctfc, Ikaros, or E2a bindings sites were higher than those without binding sites. Irrespective of the presence or absence of bindings sites for these TFs, we found that upon pre-BCR signaling interaction frequencies with the *Sis* element increased and those with the iE $\kappa$  did not change. In contrast, for the 3'E $\kappa$  we found that pre-BCR signaling specifically increased interaction frequencies with fragments occupied by Ctfc, Ikaros, or E2a.

Finally, we found that the presence of di- or trimethylation of histone 3 lysine 4 (H3K4Me2/3), an epigenetic signature associated with locus accessibility [59] and Rag-binding [60,61], also correlated with increased interaction frequencies with  $\kappa$  regulatory elements, revealing a similar pre-BCR signaling dependency as seen for the TFs analyzed (Figure 6D).

We conclude that the presence of essential TFs or H3K4Me2/3 in the  $V_{\kappa}$  region strongly correlates with the formation of long-range chromatin interactions with the  $\kappa$  regulatory elements, and that for the *Sis* and 3'E $\kappa$  elements this interaction preference is further enhanced by pre-BCR signaling.

### Proximity of $V_{\kappa}$ Genes to E2a Binding Sites Correlates with High $V_{\kappa}$ Usage and Increased Long-Range Chromatin Interactions

Since the long-range interactions with  $\kappa$  regulatory elements correlated with the presence of TFs implicated in *Igk* recombination, we next asked whether the  $\kappa$  regulatory elements preferentially interacted with  $V_{\kappa}$  genes that are in close proximity to binding sites for Ctfc, Ikaros, or E2a.

Strikingly, the majority of functional  $V_{\kappa}$  genes (95/101) was found to have an Ikaros binding site in close proximity—that is, located on the same 3C-seq restriction fragment (average length of  $\sim 3$  kb, unpublished data) (Figure 7A). Proximity of  $V_{\kappa}$  genes to an E2a binding site (37%) or H3K4Me2/3 positive region ( $\sim 28\%$ ) is more selective, while only a small fraction of  $V_{\kappa}$  genes are close to Ctfc binding sites ( $\sim 12\%$ ) ([22]; Figure 7A). All  $V_{\kappa}$  genes marked by E2a, Ctfc, H3K4Me2/3, or a combination of these also contain an Ikaros binding site. Frequently used  $V_{\kappa}$  genes ( $> 1.0\%$  usage; 33/101 genes) were located in two separate regions, a proximal and a distal region, which also contained virtually all E2a and H2K4Me2/3-marked  $V_{\kappa}$  genes (Figure 7A).

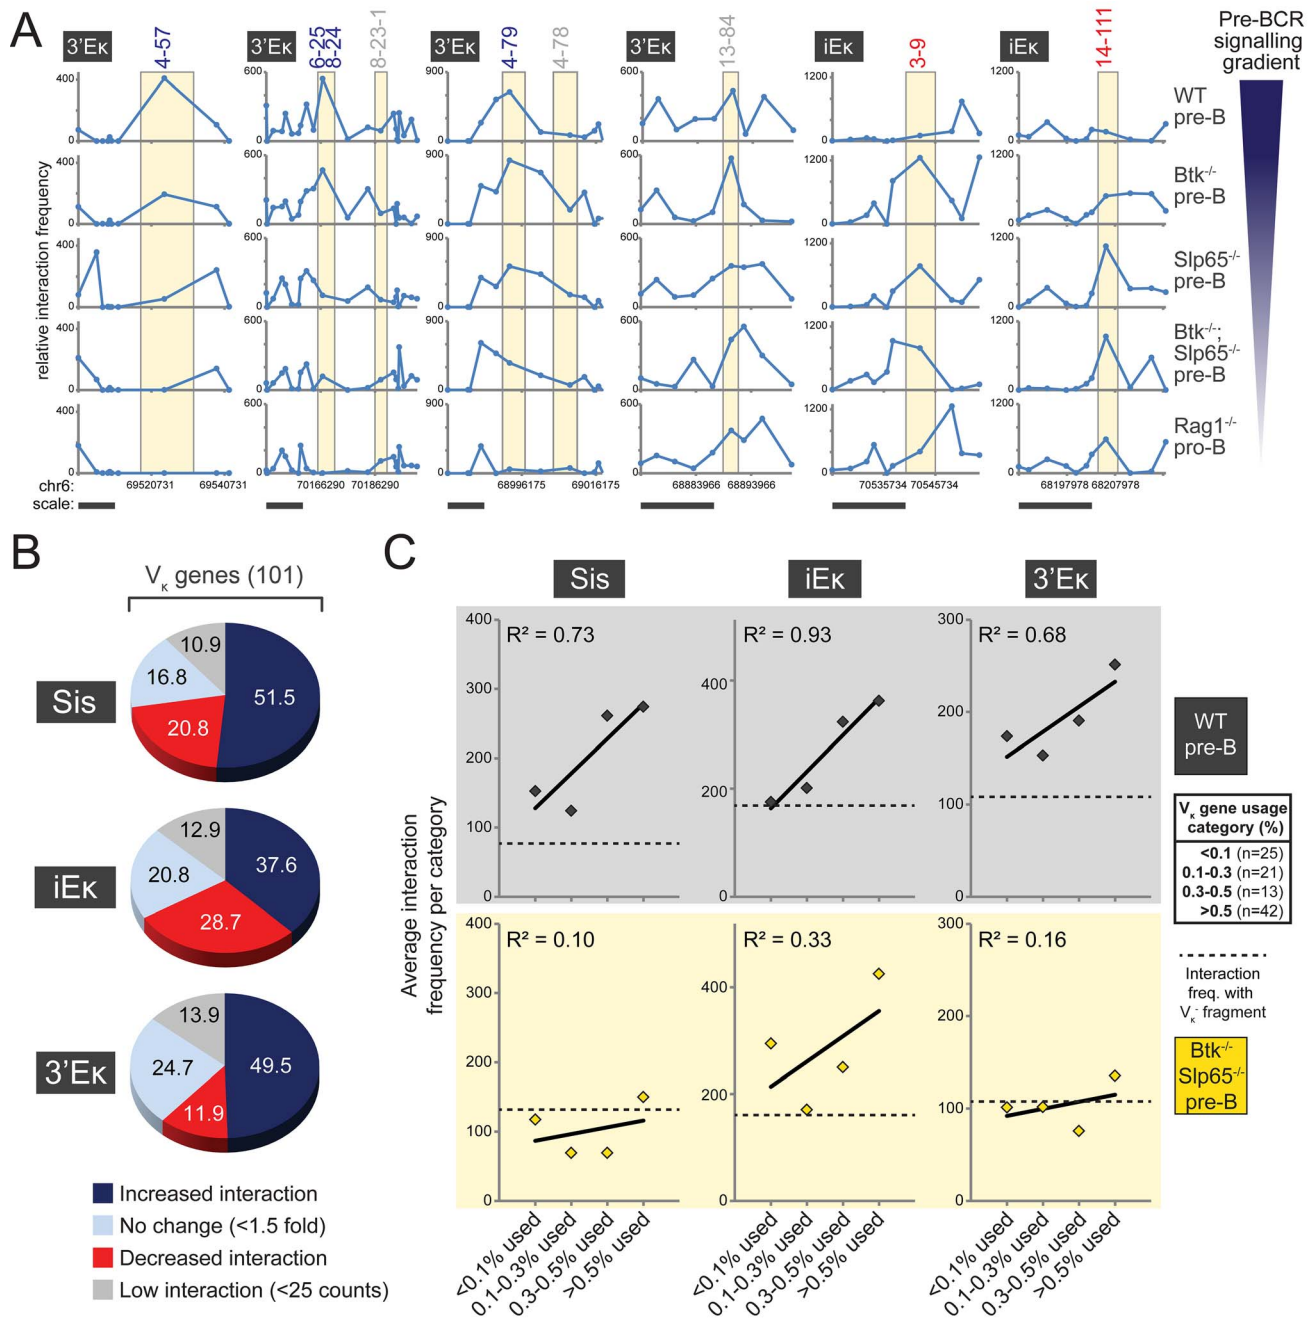

We found that  $V_{\kappa}$  genes marked by both Ikaros and E2a were used substantially more often than those only bound by Ikaros (Figure 7B), suggesting that these  $V_{\kappa}$  genes are preferentially targeted for  $V_{\kappa}$ -to-J $\kappa$  gene rearrangement. Our 3C-seq analyses showed that in WT pre-B cells, interaction frequencies with the three  $\kappa$  regulatory elements were higher for Ikaros/E2a-marked  $V_{\kappa}$  genes compared to genes marked by Ikaros binding alone (Figure 7C). In fact,  $V_{\kappa}^{+}$  restriction fragments containing an Ikaros binding site but not an E2a binding site showed interaction frequencies similar to  $V_{\kappa}^{-}$  restriction fragments. Under conditions of very low pre-BCR signaling (in *Btk*<sup>–/–</sup>*Slp65*<sup>–/–</sup> pre-B cells), we observed strongly reduced interaction frequencies of  $V_{\kappa}^{+}$  E2a binding restriction fragments with the *Sis* and 3'E $\kappa$  elements. These interaction frequencies were in the same range as those of  $V_{\kappa}^{-}$  fragments or  $V_{\kappa}^{+}$  fragments that harbored an Ikaros site only (Figure 7C). Interaction frequencies with the iE $\kappa$  enhancer, however, were independent of pre-BCR signaling. As shown in Figure 7D, for the majority of Ikaros/E2a-marked  $V_{\kappa}^{+}$  fragments (65%), pre-BCR signaling was associated with increased interactions with the *Sis* and 3'E $\kappa$  elements (comparing wild-type and *Btk*<sup>–/–</sup>*Slp65*<sup>–/–</sup> pre-B cells). In these analyses, only  $\sim 13.5\%$  and  $\sim 5.4\%$  of Ikaros/E2a-marked  $V_{\kappa}^{+}$  fragments showed a decreased interaction frequency upon pre-BCR signaling. In contrast, almost equal proportions of Ikaros/E2a-marked  $V_{\kappa}^{+}$  fragments showed increased ( $\sim 37\%$ ) and decreased ( $\sim 30\%$ ) interactions with iE $\kappa$  upon pre-BCR signaling.

Taken together, these data reveal strong positive correlations between the presence of E2a binding sites,  $V_{\kappa}$  usage, and long-range chromatin interactions with  $\kappa$  regulatory elements in pre-B cells. Remarkably, for the iE $\kappa$  element, these correlations are largely independent of *Btk*/*Slp65*-mediated pre-BCR signaling, whereas for the 3'E $\kappa$  they are completely dependent on signaling.

## Discussion

During B-cell development the pre-BCR checkpoint is known to regulate the expression of many genes, part of which control the increase in *Igk* locus accessibility to the V(D)J recombinase complex. However, it remained unknown how pre-BCR signaling events affect accessibility in terms of *Igk* locus contraction and topology.

Here we identified numerous genes involved in *IgL* chain recombination, chromatin modification, signaling, and cell survival to be aberrantly expressed in pre-B cells lacking the pre-BCR signaling molecules *Btk* and/or *Slp65*. We found that GLT over the  $V_{\kappa}$  region, reflecting  $V_{\kappa}$  accessibility, is strongly reduced in these cells. We used 3C-Seq to show that in pro-B cells both the intronic and the 3'  $\kappa$  enhancers frequently interact with the  $\sim 3.2$  Mb  $V_{\kappa}$  region, as well as with *Igk* flanking sequences, indicating that the *Igk* locus is already contracted at the pro-B cell stage. 3C-Seq analyses in wild-type and *Btk*/*Slp65* single- and double-deficient pre-B cells demonstrated that pre-BCR signaling significantly affects *Igk* locus topology. First, pre-BCR signaling

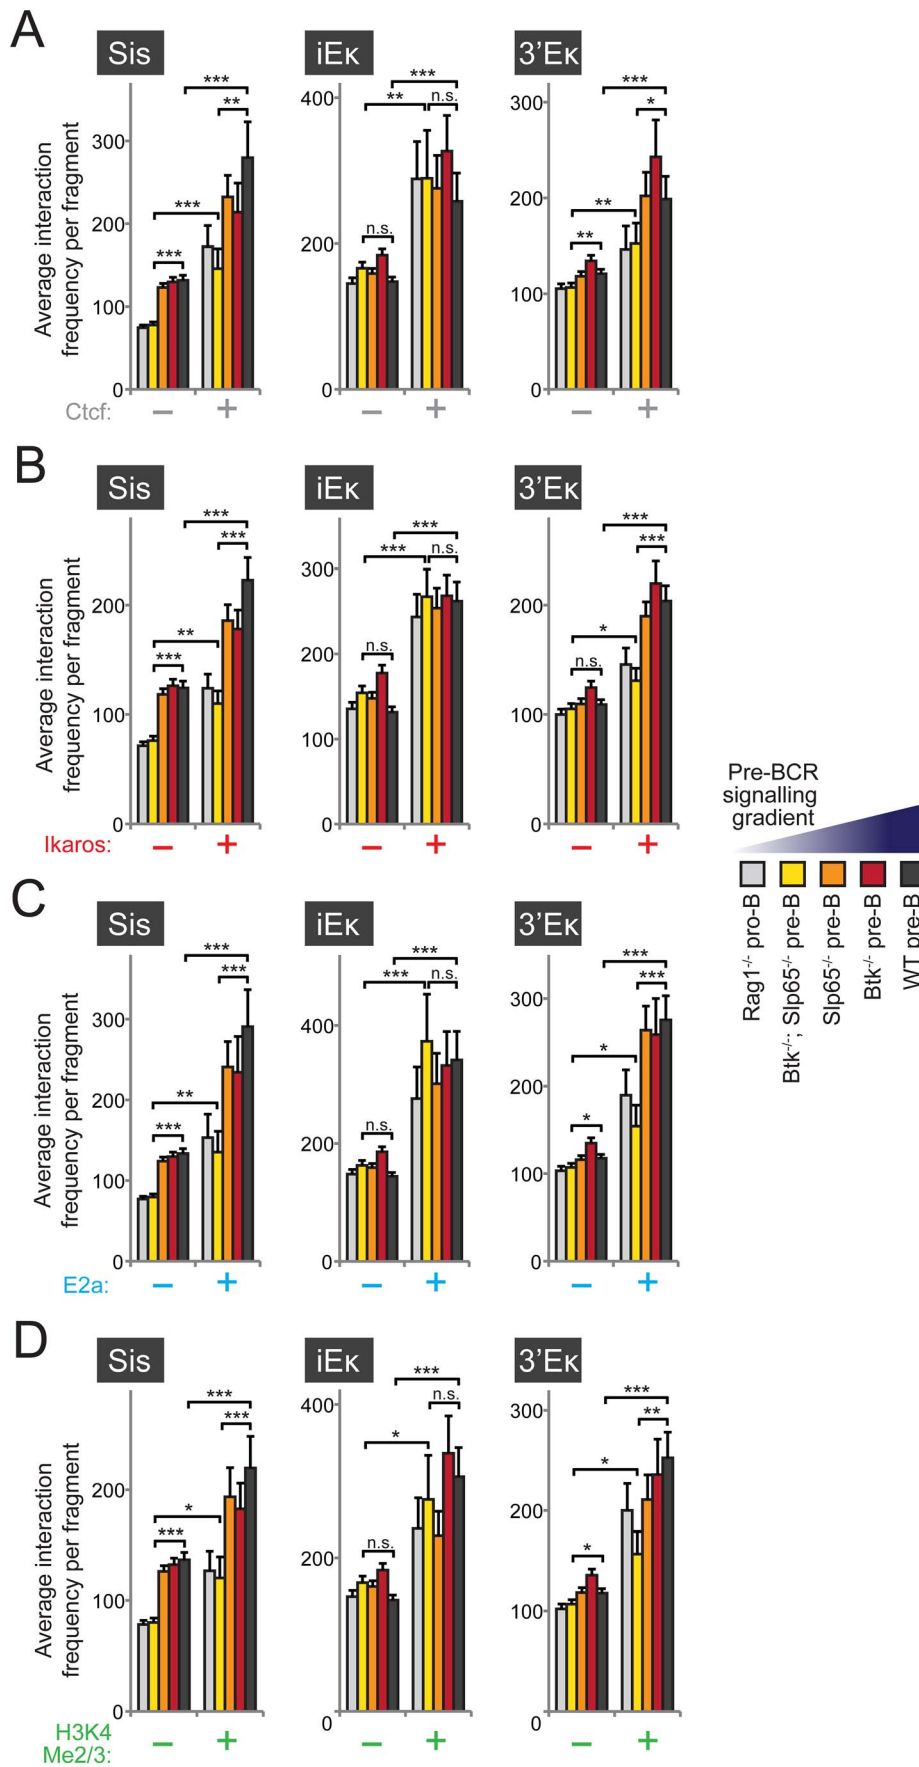

**Figure 5. Long-range chromatin interactions of  $\kappa$  regulatory elements correlate with  $V_{\kappa}$  gene usage.** (A) Selected examples of genomic regions containing  $V_{\kappa}^{+}$  fragments, showing increased ( $V_{\kappa}4-57$ ,  $V_{\kappa}6-25$ ,  $V_{\kappa}8-24$ ,  $V_{\kappa}4-79$ ), stable ( $V_{\kappa}8-23-1$ ,  $V_{\kappa}4-78$ ,  $V_{\kappa}13-84$ ), or decreased ( $V_{\kappa}3-9$ ,  $V_{\kappa}14-111$ ) 3C-seq interaction frequencies with 3'Eκ or iEκ upon pre-BCR signaling. Averaged 3C-seq signals are plotted as a line graph, with the individual data points representing the center of the BglII restriction fragments. Yellow shading marks the BglII fragment on which the  $V_{\kappa}$  gene(s) is located.  $V_{\kappa}$  gene(s) are indicated (top) and chromosomal coordinates and scale bars (10 kb) are plotted (bottom). (B) Classification of  $V_{\kappa}^{+}$  fragments, based on the effect of pre-BCR signaling on their interactions with the three  $\kappa$  regulatory elements indicated. Increase and decrease were defined as >1.5-fold change of interaction frequencies detected in WT pre-B cells versus *Btk*<sup>-/-</sup> *Slp65*<sup>-/-</sup> pre-B cells. (C) Correlation of average interaction frequencies (for the three  $\kappa$  regulatory elements indicated) with four  $V_{\kappa}$  usage categories ranging from low (<0.1%) to high usage (>0.5%, listed in the table on the right). Diamonds represent average interaction frequencies for *Btk*<sup>-/-</sup> *Slp65*<sup>-/-</sup> pre-B cells (yellow) and WT pre-B cells (grey). The dotted line in each graph depicts the average interaction frequency with fragments that do not contain a functional  $V_{\kappa}$  ( $V_{\kappa}^{-}$ ). Primary  $V_{\kappa}$  gene usage data were taken from [54].

doi:10.1371/journal.pbio.1001791.g005

reduces the interactions of the intronic and 3'κ enhancers with *Igκ* flanking regions, effectively focusing enhancer action towards the  $V_{\kappa}$  region to facilitate  $V_{\kappa}$ -to- $J_{\kappa}$  recombination. Second, pre-BCR signaling strongly increases nuclear proximity of the 3'κ enhancer

to  $V_{\kappa}$  genes, whereby this increase is more substantial for more frequently used  $V_{\kappa}$  genes and for  $V_{\kappa}$  genes close to a binding site for the basic helix-loop-helix protein E2a. Third, pre-BCR signaling augments interactions between κ regulatory elements

**Figure 6. Long-range chromatin interactions of  $\kappa$  regulatory elements correlate with TF binding and histone modifications.** (A–D) For fragments within the  $V_{\kappa}$  region, average 3C-seq interaction frequencies were calculated for fragments that did (+) or did not (–) contain binding sites for TFs or H3K4 histone modifications (as determined by previous ChIP-Seq studies; see Materials and Methods for references). Data for the three viewpoint and the five B-cell precursor fractions representing a pre-BCR signaling gradient are shown for Ctf (A), Ikaros (B), E2a (C), and H3K4 di- and tri-methylation (Me2/3). Statistical significance was determined using a Mann–Whitney U test (\* $p < 0.05$ ; \*\* $p < 0.01$ ; \*\*\* $p < 0.001$ ; n.s., not significant,  $p \geq 0.05$ ).

doi:10.1371/journal.pbio.1001791.g006

and fragments within the  $V_{\kappa}$  region bound by the key B-cell TFs Ikaros and E2a and the architectural protein Ctf. Fourth, pre-BCR signaling has limited effects on interactions of the intronic  $\kappa$  enhancer with fragments within the *Igk* locus, as this enhancer already displays interaction specificity for functional  $V_{\kappa}$  genes and TF-bound regions in pro-B cells. Fifth, pre-BCR signaling has limited effects on the interactions between the intronic or 3'  $\kappa$  enhancers and fragments that do not contain a  $V_{\kappa}$  gene or an Ikaros, E2a, or Ctf binding site, emphasizing the specificity of pre-BCR signaling-induced changes in *Igk* locus topology. Sixth, pre-BCR signaling appears to induce mutual regulatory coordination between the three regulatory elements, as their interaction profiles with individual  $V_{\kappa}$  genes become highly correlated upon signaling. Finally, pre-BCR signaling increases interactions of the *Sis* element with DNA fragments in the *Igk* locus, irrespective of the presence of a  $V_{\kappa}$  gene or TF. Collectively, our findings demonstrate that pre-BCR signals relayed through Btk and Slp65 are required to create a chromatin environment that facilitates proper *Igk* locus recombination. This multistep process is initiated by up-regulation of key TFs like Aiolos, Ikaros, Irf4, and E2a. These proteins are then recruited to or further accumulate at the *Igk* locus and its regulatory elements, resulting in a specific fine-tuning of enhancer-mediated locus topology that increases locus accessibility to the Rag recombinase proteins.

Importantly, the presence of strong lineage-specific interaction signals between the  $C_{\kappa}$ /enhancer region and distal  $V_{\kappa}$  genes in pro-B cells indicates that the *Igk* locus is already contracted at this stage. In contrast to a previous microscopy study indicating that *Igk* locus contraction did not occur until the small pre-B cell stage [36], our 3D DNA FISH analysis indeed detected similar nuclear distances between distal  $V_{\kappa}$  and the  $C_{\kappa}$ /enhancer region in cultured pro-B and pre-B cells. Recently Hi-C was employed to study global early B cell genomic organization whereby substantial interaction frequencies were found between the intronic  $\kappa$  enhancer and the  $V_{\kappa}$  region in pro-B cells [40]. E2a-deficient pre-pro-B cells, which are not yet fully committed to the B-cell lineage [62], showed very few interactions among the iE $\kappa$  and the distal part of the  $V_{\kappa}$  region [40], resembling the interactions we observed in nonlymphoid cells (Figure 3A). Accordingly, 3D-FISH analysis showed that the *Igk* locus adopted a noncontracted topology in these pre-pro-B cells (Figure 3B). These data indicate that *Igk* locus contraction is already achieved in pro-B cells and depends on the presence of E2a. Supporting this notion, active histone modifications and E2a were already detected at the  $\kappa$  enhancers and  $V_{\kappa}$  genes at the pro-B cell stage [56,63], whereby E2a was frequently found at the base of long-range chromatin interactions together with Ctf and Pu.1, possibly acting as “anchors” to organize genome topology [40]. The observed correlation between E2a binding,  $V_{\kappa}$  gene usage and iE $\kappa$  proximity in pro-B cells (Figure 5C, Figure 7C) further strengthens an early critical role for E2a in regulating *Igk* locus topology,  $V_{\kappa}$  gene accessibility, and recombination.

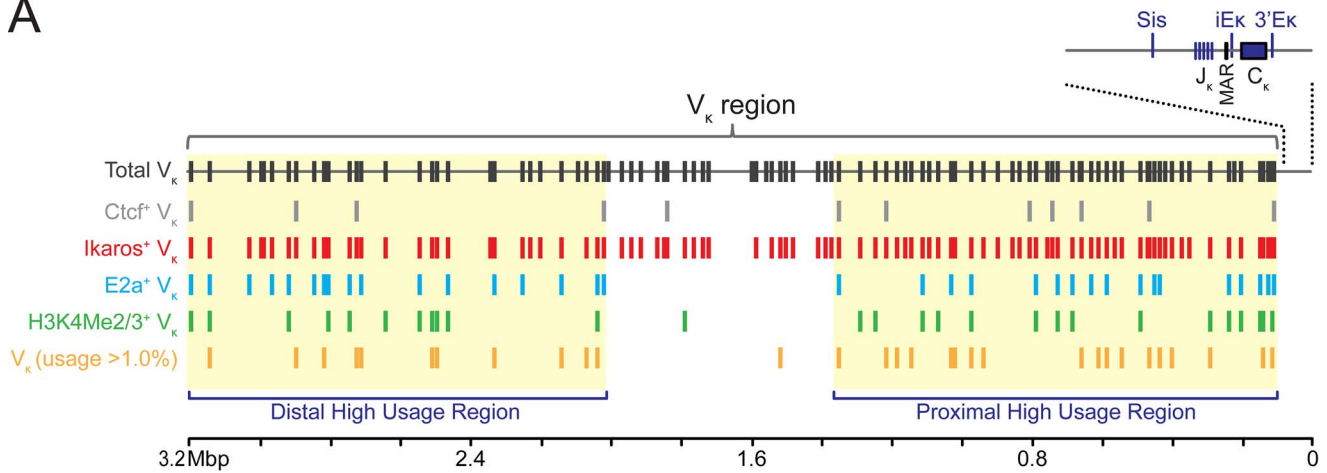

Our 3C-seq experiments revealed that pre-BCR signaling is not required to induce long-range interactions between the  $\kappa$  regulatory elements and distal parts of the  $V_{\kappa}$  locus, indicating that TFs strongly induced by signaling—that is, Aiolos, Ikaros, and

Irf4—are not strictly necessary to form a contracted *Igk* locus. Prime candidates for achieving *Igk* locus contraction at the pro-B cell stage are E2a and Ctf, as they have been implicated in regulating *Ig* locus topology [21,40,64,65] and E2a already marks frequently used  $V_{\kappa}$  genes at the pro-B cell stage (Figure 7), although we did observe reduced E2a expression and binding to the iE $\kappa$  enhancer and  $V_{\kappa}$  genes when pre-B cell signaling was low (Figure 1 and Table S3), suggesting that pre-BCR signaling is required for high-level E2a occupancy of the  $V_{\kappa}$  genes. We previously reported that *Igk* gene recombination can occur in the absence of Ctf and that Ctf mainly functions to limit interactions of the  $\kappa$  enhancers with proximal  $V_{\kappa}$  regions and to prevent inappropriate interactions between these strong enhancers and elements outside the *Igk* locus [21]. Because at the pro-to-pre-B cell transition Aiolos, Ikaros, and Irf4 are recruited to the *Igk* locus and histone acetylation and H3K4 methylation increases [17,38,63,66], we hypothesize that pre-BCR-induced TFs act upon an E2a/Ctf-mediated topological scaffold to further refine the long-range chromatin interactions of the  $\kappa$  regulatory elements. Hereby, these TFs mainly act to focus and to coordinate the interactions of the two  $\kappa$  enhancers to the  $V_{\kappa}$  gene segments, in particular to frequently used  $V_{\kappa}$  genes, thereby increasing their accessibility for recombination (see Figure 7E for a model of pre-BCR signaling-induced changes in *Igk* locus accessibility).

In this context, our 3C-seq data show that the two  $\kappa$  enhancer elements have distinct roles. Both 3'E $\kappa$  and iE $\kappa$  elements manifest interaction specificity for highly used, E2a-marked,  $V_{\kappa}$  genes. However, whereas iE $\kappa$  already shows this specificity in pro-B cells (although pre-BCR signaling does augment this specificity), 3'E $\kappa$  only does so in pre-B cells upon pre-BCR signaling. These observations indicate that iE $\kappa$  is already “prefocused” at the pro-B cell stage and that pre-BCR signals are required to fully activate and focus the 3'E $\kappa$  to allow synergistic promotion of *Igk* recombination by both enhancers (see Figure 7E) [52]. In agreement with such distinct sequential roles, iE $\kappa$  and not the 3'E $\kappa$  was found to be required for the initial increase in *Igk* locus accessibility, which occurred upon binding of E2a only [37,38,67]. The 3'E $\kappa$  on the other hand requires binding of pre-BCR signaling-induced Irf4 to promote locus accessibility [19,38], followed by further recruitment of E2a to both  $\kappa$  enhancers and highly used  $V_{\kappa}$  genes (Table S3 and [38,57]).

The *Sis* regulatory element was shown to dampen proximal  $V_{\kappa}$ – $J_{\kappa}$  rearrangements and to specify the targeting of *Igk* transgenes to centromeric heterochromatin in pre-B cells [20]. As *Sis* is extensively occupied by the architectural Ctf protein and deletion of *Sis* or Ctf both resulted in increased proximal  $V_{\kappa}$  usage [21,23], it was postulated that *Sis* functions as a barrier element to prevent the  $\kappa$  enhancers from too frequently targeting proximal  $V_{\kappa}$  genes for recombination. In this context, we now provide evidence that interactions between the proximal  $V_{\kappa}$  genes, *Sis*, and iE $\kappa$ —but not 3'E $\kappa$ —are already coordinated before pre-BCR signaling occurs (Figure S9). Perhaps not surprisingly, *Sis*-mediated long-range chromatin interactions displayed a pattern and pre-BCR signaling response that was different from the  $\kappa$  enhancers. Unlike for the enhancers, upon pre-BCR signaling, *Sis*-mediated interactions with regions outside the *Igk* locus were maintained and

**Figure 7. Proximity of  $V_{\kappa}$  genes to E2a binding sites correlates with frequencies of long-range interactions.** (A) Schematic representation of the Ig $\kappa$  locus, showing the location of all functional  $V_{\kappa}$  (grey, top),  $J_{\kappa}$  and  $C_{\kappa}$  gene segments, and the  $\kappa$  regulatory elements Sis, iE $\kappa$ , and 3'E $\kappa$ . MAR, matrix attachment region.  $V_{\kappa}$  genes within close proximity (as defined by colocalization on the same 3C-Seq restriction fragment) to the indicated TFs or H3K4 hypermethylation (as detected by previous ChIP-seq studies; see Materials and Methods for references) are shown. At the bottom, highly used ( $>1.0\%$  used)  $V_{\kappa}$  gene segments are depicted (orange), which cluster within two large high-usage domains (yellow shading). Primary  $V_{\kappa}$  gene usage data was taken from [54]. (B) Average usage of  $V_{\kappa}$  genes marked only by an Ikaros binding site or those marked by binding sites of both Ikaros and E2a. (C) Comparison of average interaction frequencies (for the three  $\kappa$  regulatory elements indicated) between  $V_{\kappa}^{-}$  fragments (no  $V_{\kappa}$ ),  $V_{\kappa}^{+}$  fragments containing an Ikaros binding site only, and  $V_{\kappa}^{+}$  fragments containing both an Ikaros and E2a binding site. Bars represent average frequencies for *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cells (yellow) and WT pre-B cells (grey). (D) Classification of  $V_{\kappa}^{+}$  fragments, containing an Ikaros binding site only (top) or containing both an Ikaros and E2a binding site (bottom), based on the effect of pre-BCR signaling on their interactions with the three  $\kappa$  regulatory elements indicated. Increase and decrease were defined as  $>1.5$ -fold change of interaction frequencies detected in WT pre-B cells versus *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cells. (E) Proposed model of pre-BCR signaling-mediated changes in  $\kappa$  enhancer action. In pro-B cells (left) the enhancers show minimal coordination and their interactions are not yet (fully) focused on the  $V_{\kappa}$  genes. Upon pre-BCR signaling and differentiation to pre-B cells (right), TFs bind the locus to coordinate enhancer action and focus their interactions to the  $V_{\kappa}$  genes, inducing germline transcription (GLT) and accessibility to the V(D)J recombinase. See Discussion for more details. Statistical significance was determined using a Mann-Whitney U test (\* $p<0.05$ ; \*\* $p<0.01$ ; \*\*\* $p<0.001$ ; n.s., not significant,  $p\geq 0.05$ ). doi:10.1371/journal.pbio.1001791.g007

interaction within the  $V_{\kappa}$  region increased, irrespective of the presence of  $V_{\kappa}$  genes or TF binding sites. Because Sis is involved in targeting the nonrecombining Ig $\kappa$  allele to heterochromatin [20], the observed interaction pattern of the Sis element might reflect its action in pre-B cells to sequester the nonrecombining Ig $\kappa$  locus and target it towards heterochromatin. This might also explain the increased interaction frequencies of Sis with highly used  $V_{\kappa}$  genes upon pre-BCR signaling (Figures 5C and 7C), as such highly accessible genes likely require an even tighter association with Sis and heterochromatin to prevent undue recombination.

Surprisingly, we observed a striking correlation between Ikaros binding and  $V_{\kappa}$  gene location (94% of  $V_{\kappa}$  genes were in close proximity to an Ikaros binding site; Figure 7A). Although Ikaros and Aiolo have a positive role in regulating gene expression during B-cell development [55,58] and Ikaros is required for IgH and IgL recombination [39,58], Ikaros has also been reported to silence gene expression through its association with pericentromeric heterochromatin [68] or through recruitment of repressive cofactor complexes [69,70]. Recruitment of Ikaros to the Ig $\kappa$  locus was found increased in pre-B cells as compared to pro-B cells [63], in agreement with its up-regulation in pre-B cells (Figure 1). Furthermore, Ikaros binds the Sis element, where it was suggested to mediate heterochromatin targeting of Ig $\kappa$  alleles by the Sis region [20]. Aiolo, although not essential for B-cell development like Ikaros [58,71], is strongly induced by pre-B cell signaling and has been reported to cooperate with Ikaros in regulation gene expression [27]. Although their synergistic role during IgL chain recombination has not been extensively studied, the Ikaros/Aiolo ratio changes upon pre-BCR signaling (Figure 1). Increased recruitment of Ikaros/Aiolo to  $V_{\kappa}$  genes and the  $\kappa$  enhancers likely increases Ig $\kappa$  locus accessibility and contraction (see Figure 6), as Ikaros was very recently shown to be essential for IgL recombination [58]. On the other hand, it is conceivable that on the nonrecombining allele, increased recruitment of Ikaros/Aiolo to  $V_{\kappa}$  genes and the Sis region could facilitate silencing of this allele. Further investigations using allele-specific approaches [72] will be required to clarify the allele-specific action of the Sis element during Ig $\kappa$  recombination.

In summary, by investigating the effects of a pre-BCR signaling gradient—rather than deleting individual TFs—we have taken a more integrative approach to study the regulation of Ig $\kappa$  locus topology. Our 3C-Seq analyses in wild-type, *Btk*, and *Slp65* single- and double-deficient pre-B cells show that interaction frequencies between Sis, iE $\kappa$ , or 3'E $\kappa$  and the  $V_{\kappa}$  region are already high in pro-B cells and that pre-BCR signaling induces accessibility through a functional redistribution of long-range chromatin interactions within the  $V_{\kappa}$  region, whereby the iE $\kappa$  and 3'E $\kappa$  enhancer elements play distinct roles.

## Materials and Methods

### Mice

VH81x transgenic mice [73] on the *Rag-1*<sup>-/-</sup> background [74] that were either wild-type, *Btk*<sup>-/-</sup> [75], *Slp65*<sup>-/-</sup> [42], or *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> have been previously described [34]. Mice were crossed on the C57BL/6 background for  $>8$  generations, bred, and maintained in the Erasmus MC animal care facility under specific pathogen-free conditions and were used at 6–13 wk of age. Experimental procedures were reviewed and approved by the Erasmus University Committee of Animal Experiments.

### Flow Cytometry

Preparation of single-cell suspensions and incubations with monoclonal antibodies (mAbs) were performed using standard procedures. Bone marrow B-lineage cells were purified using fluorescein isothiocyanate (FITC)-conjugated anti-B220(RA3-6B2) and peridinin chlorophyll protein (PCP)-conjugated anti-CD19, together with biotinylated mAbs specific for lineage markers Gr-1, Ter119, and CD11b and APC-conjugated streptavidin as a second step to further exclude non-B cells. Cells were sorted with a FACSARIA (BD Biosciences). The following mAbs were used for flow cytometry: FITC-, PerCP-anti-B220 (RA3-6B2), phycoerythrin (PE)-anti-CD2 (LFA-2), PCP-, allophycocyanin (APC)- or APC-Cy7-anti-CD19 (ID3), PE-, or APC anti-CD43 (S7). All these antibodies were purchased from BD Biosciences or eBiosciences. Samples were acquired on an LSRII flow cytometer (BD Biosciences) and analyzed with FlowJo (Tree Star) and FACSDiva (BD Biosciences) software.

### Quantitative RT-PCR and DNA Microarray Analysis

Extraction of total RNA, reverse-transcription procedures, design of primers, and cDNA amplification have been described previously [21]. Gene expression was analyzed using an ABI Prism 7300 Sequence Detector and ABI Prism Sequence Detection Software version 1.4 (Applied Biosystems). All PCR primers used for quantitative RT-PCR of TFs or  $\kappa^0$ ,  $\lambda^0$ , and  $V_{\kappa}$  GLT are described in [21], except for Obf1 (forward 5'-CCTGGCCACC-TACAGCAC-3', reverse 5'-GTGGAAGCAGAAA CCTCCAT-3', obtained from the Roche Universal Probe Library).

Biotin-labeled cRNA was hybridized to the Mouse Gene 1.0 ST Array according to the manufacturer's instructions (Affymetrix); data were analyzed with BRB-ArrayTools (version 3.7.0, National Cancer Institute) using Affymetrix CEL files obtained from GCOS (Affymetrix). The RMA approach was used for normalization. The TIGR MultiExperiment Viewer software package (MeV version 4.8.1) was used to perform data analysis and visualize results [45]. One-way ANOVA analysis of the five experimental groups of B

cells was used to identify genes significantly different from wild-type VH81X Tg *Rag1*<sup>-/-</sup> pre-B cells ( $p < 0.01$ ).

### Chromatin Immunoprecipitation (ChIP)

ChIP experiments were performed as previously described [76] using FACS sorted bone marrow pre-B cell fractions (0.3–2.0 million cells per ChIP). Antibodies against E2a (sc-349, Santa Cruz Biotechnology) and Ikaros (sc-9861, Santa Cruz Biotechnology) were used for immunoprecipitation. Purified DNA was analyzed by quantitative RT-PCR as described above. Primer sequences are available on request.

### Chromosome Conformation Capture Coupled to High-Throughput Sequencing (3C-Seq)

3C-Seq experiments were essentially carried out as described previously [21,41]. For 3C-Seq library preparation, *Bgl*II was used as the primary restriction enzyme and *Nla*III as a secondary restriction enzyme. 3C-seq template was prepared from WT E13.5 fetal liver erythroid progenitors and FACS-sorted bone marrow pro-B cell or pre-B cell fractions (see above) from pools of 4–6 mice. In total, between 1 and 8 million cells were used for 3C-seq analysis. Primers for the Sis, iEk, and 3'Ek viewpoint-specific inverse PCR were described previously [21]. 3C-seq libraries were sequenced on an Illumina Hi-Seq 2000 platform. 3C-Seq data processing was performed as described elsewhere [41,77]. Two replicate experiments were sequenced for each genotype and viewpoint, and normalized interaction frequencies per *Bgl*III restriction fragment were averaged between the two experiments.

For quantitative analysis, the *Igk* locus and surrounding sequences were divided into three parts (mm9 genome build): a ~2 Mb upstream region (chr6:65,441,978–67,443,029; 759 fragments), a ~3.2 Mb *V<sub>κ</sub>* region (chr6:67,443,034–70,801,754; 1,290 fragments) and a downstream ~3.2 Mb region (chr6:70,801,759–73,993,074; 1,143 fragments). For each cell type (as described above) sequence read counts within individual *Bgl*III restriction fragments were normalized for differences in library size (expressed as “reads per million”; see [74]) and averaged between the two replicates before further use in the various calculations. Very small *Bgl*III fragments (<100 bp) were excluded from the analysis. Fragments in the immediate vicinity of the regulatory elements (chr6:70,659,392–70,693,183; 10 fragments) were also excluded because of high levels of noise around the viewpoint, a characteristic of all 3C-based experiments. *V<sub>κ</sub>* gene coordinates (both functional genes and pseudogenes) were obtained from IMGT [11] and NCBI (Gene ID: 243469) databases. *V<sub>κ</sub>* gene usage data (C57BL/6 strain, bone marrow) were obtained from [54]. ChIP-seq datasets were obtained from [21] (Ctcf), [55] (Ikaros), and [56] (E2a, H3K4Me2, and H3K4Me3). *V<sub>κ</sub>* genes were scored positive for TF binding sites or for a histone modification, if they were located on the same *Bgl*III restriction fragment (corresponding to the 3C-Seq analysis).

### 3D DNA Immuno-FISH

*Rag1*<sup>-/-</sup> pro-B and *Rag1*<sup>-/-</sup>;VH81X pre-B cells were isolated from femoral bone marrow suspensions by positive enrichment of CD19<sup>+</sup> cells using magnetic separation (Miltenyi Biotec). Cells were cultured for 2 wk in Iscove's Modified Dulbecco's medium containing 10% fetal calf serum, 200 U/ml penicillin, 200 mg/ml streptomycin, 4 nM L-glutamine, and 50 μM β-mercaptoethanol, supplemented with IL-7 and stem cell factor at 2 ng/ml. *E2a*<sup>-/-</sup> hematopoietic progenitors were grown as described previously [78]. Prior to 3D-FISH analysis, cells were characterized by flow

cytometric analysis of CD43, CD19, and CD2 surface marker expression to verify their phenotype (Figure S6).

3D DNA FISH was performed as described previously [79] with BAC clones RP23-234A12 and RP23-435I4 (located at the distal end of the *V<sub>κ</sub>* region and at the *C<sub>κ</sub>*/enhancer region, respectively; Figure 3A) obtained from BACPAC Resources (Oakland, CA). Probes were directly labeled with Chromatide Alexa Fluor 488-5 dUTP and Chromatide Alexa Fluor 568-5 dUTP (Invitrogen) using Nick Translation Mix (Roche Diagnostics GmbH).

Cultured primary cells were fixed in 4% paraformaldehyde, and permeabilized in a PBS/0.1% Triton X-100/0.1% saponin solution and subjected to liquid nitrogen immersion following incubation in PBS with 20% glycerol. The nuclear membranes were permeabilized in PBS/0.5% Triton X-100/0.5% saponin prior to hybridization with the DNA probe cocktail. Coverslips were sealed and incubated for 48 h at 37°C, washed, and mounted on slides with 10 μl of Prolong gold anti-fade reagent (Invitrogen).

Pictures were captured with a Leica SP5 confocal microscope (Leica Microsystems). Using a 63× lens (NA 1.4), we acquired images of ~70 serial optical sections spaced by 0.15 μm. The datasets were deconvolved and analyzed with Huygens Professional software (Scientific Volume Imaging, Hilversum, the Netherlands). The 3D coordinates of the center of mass of each probe were transferred to Microsoft Excel, and the distances separating each probe were calculated using the equation:  $\sqrt{(X_a - X_b)^2 + (Y_a - Y_b)^2 + (Z_a - Z_b)^2}$ , where X, Y, and Z are the coordinates of object a or b.

### Statistical Analysis

Statistical significance was analyzed using a nonparametric Mann–Whitney U test (IBM SPSS Statistics 20). The  $p$  values < 0.05 were considered significant.

### Accession Numbers

3C-seq and microarray expression datasets have been submitted to the Sequence Read Archive (SRA, accession number SRP032509) and Gene Expression Omnibus (GEO, accession number GSE53896), respectively.

### Supporting Information

**Figure S1 Gene distance matrix analysis using gene expression profiling data from pre-B/pro-B cell fractions representing a pre-BCR signaling gradient.** Microarray expression profiling was performed on three or four independent FACS-purified B220<sup>+</sup>CD19<sup>+</sup> pre-B cell fractions from wild-type (WT), *Btk*, and *Slp65* single- and double-deficient VH81x transgenic *Rag1*<sup>-/-</sup> mice (see Figure 1 for gating strategy). The TIGR Multi Experiment Viewer software package (MeV version 4.8.1) was used to perform a one-way ANOVA analysis ( $p < 0.01$ ) and identify genes differentially expressed within the five B-cell fractions (versus VH81X Tg *Rag1*<sup>-/-</sup> pre-B cells). The software was subsequently used to create a gene distance matrix of highly significant genes, resulting in the depicted plot. Differences in gene expression profiles are depicted as a color code; darker colors indicate greater similarity, and brighter colors less similarity between groups. Consistent with the unsupervised clustering analysis shown in Figure 1B, a clear gene expression gradient among the five B cell groups emerges in which *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B and *Rag1*<sup>-/-</sup> pro-B cells show highly comparably expression signatures. (TIF)

**Figure S2 Locus-wide 3C-Seq analysis of the *Igk* region (Sis viewpoint) plotted as line graphs.** Overview

of long-range interactions revealed by 3C-Seq experiments performed on the indicated cell fractions, representing a gradient of pre-BCR signaling. Shown are the relative interaction frequencies (average of two replicate experiments) for the Sis viewpoint per 100 kb region across the *Igκ* locus, plotted as line graphs. The bottom graph shows an overlay of the WT and *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cell interaction frequencies. The ~8.4 Mb region containing the *Igκ* locus (yellow shading) and flanking regions (cyan shading) is depicted. Pre-B cell fractions were FACS-purified from the indicated mice on a VH81x transgenic *Rag1*<sup>-/-</sup> background (see Figure 1 for gating strategy). (TIF)

**Figure S3 Locus-wide 3C-Seq analysis of the *Igκ* region (iEκ viewpoint) plotted as line graphs.** Overview of long-range interactions revealed by 3C-Seq experiments performed on the indicated cell fractions, representing a gradient of pre-BCR signaling. Shown are the relative interaction frequencies (average of two replicate experiments) for the iEκ viewpoint per 100 kb region across the *Igκ* locus, plotted as line graphs. The bottom graph shows an overlay of the WT and *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cell interaction frequencies. The ~8.4 Mb region containing the *Igκ* locus (yellow shading) and flanking regions (cyan shading) is depicted. Pre-B cell fractions were FACS-purified from the indicated mice on a VH81x transgenic *Rag1*<sup>-/-</sup> background (see Figure 1 for gating strategy). (TIF)

**Figure S4 Locus-wide 3C-Seq analysis of the *Igκ* region (3'Eκ viewpoint) plotted as line graphs.** Overview of long-range interactions revealed by 3C-Seq experiments performed on the indicated cell fractions, representing a gradient of pre-BCR signaling. Shown are the relative interaction frequencies (average of two replicate experiments) for the 3'Eκ viewpoint per 100 kb region across the *Igκ* locus, plotted as line graphs. The bottom graph shows an overlay of the WT and *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cell interaction frequencies. The ~8.4 Mb region containing the *Igκ* locus (yellow shading) and flanking regions (cyan shading) is depicted. Pre-B cell fractions were FACS-purified from the indicated mice on a VH81x transgenic *Rag1*<sup>-/-</sup> background (see Figure 1 for gating strategy). (TIF)

**Figure S5 Selected zoom-in pictures of the 3C-seq data in the *Igκ* locus and its upstream and downstream regions.** (A) Map of the ~8.4 Mb genomic region containing the *Igκ* locus (yellow shading) and flanking regions (cyan shading). Chromosomal coordinates and gene and viewpoint locations are also depicted. Locations of the zoom-in regions shown in (B) are represented as colored rectangles (red, upstream; green, downstream; dark grey, *Igκ* locus). (B) Average interaction frequencies per BglII fragment (average of two replicate experiments) of the three regulatory elements with selected regions upstream, downstream, and within the *Igκ* locus. Data from the five B cell precursor fractions representing a pre-BCR signaling gradient are shown. Complete locus-wide 3C-seq data can be found in Figure 3 (plotted per individual BglII fragment) or Figures S2, S3, and S4 (plotted per 100 kb region). enh., enhancers. (TIF)

**Figure S6 Phenotypic characterization of cultured pre-pro-B, pro-B, and pre-B cells.** Representative FACS analysis of CD43/CD19 (A) and CD22/CD19 (B) surface marker expression on IL-7 cultured *E2a*<sup>-/-</sup> pre-pro-B, *Rag1*<sup>-/-</sup> pro-B, and VH81x *Rag1*<sup>-/-</sup> pre-B cells prior to 3D-FISH experiments. (TIF)

**Figure S7 Pre-BCR signaling is associated with an increase in the ratio of interactions inside the *Igκ* locus over interactions outside the *Igκ* locus.** The differential effects of pre-BCR signaling on long-range chromatin interactions of the iEκ, 3'Eκ, and Sis elements, as measured in 3C-seq datasets, were quantified (see Figure 4A). For all three regulatory elements, the y-axis shows the ratio of the average interaction frequencies per BglII fragment inside the ~3.2 Mb *Igκ* locus over the average interaction frequencies per BglII fragment in the flanking regions (~2.0 Mb upstream together with 3.2 Mb downstream). Analyses of the five groups of B cell precursors, representing a gradient of pre-BCR signaling, are shown, revealing that pre-BCR signaling is associated with a preference for interaction with fragments inside the V<sub>κ</sub> region over fragments outside the V<sub>κ</sub> region. (TIF)

**Figure S8 Interaction frequencies of κ regulatory elements with nonfunctional V<sub>κ</sub> genes as measured in B cell fractions representing a pre-BCR signaling gradient.** Quantitative analysis of 3C-Seq datasets obtained for the five B cell precursor fractions representing a pre-BCR signaling gradient, using the three indicated κ regulatory elements as viewpoints. Average interaction frequencies within the V<sub>κ</sub> region were determined for fragments that do not contain any V<sub>κ</sub> gene ("no V<sub>κ</sub>"), those that contain a nonfunctional V<sub>κ</sub> gene ("pseudo V<sub>κ</sub>"), and those that contain a functional V<sub>κ</sub> gene ("functional V<sub>κ</sub>"). See Materials and Methods section for more details on analysis methods. Statistical significance was determined using a Mann-Whitney U test (n.s., not significant, *p*≥0.05). (TIF)

**Figure S9 Correlations between the V<sub>κ</sub> interaction profiles of the three κ regulatory elements.** Correlation plots of average interaction frequencies of the three regulatory elements with the 101 functional V<sub>κ</sub> genes (A) or only the V<sub>κ</sub>3 gene family (B) are shown for WT pre-B cells (top, gray labels) versus *Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cells (bottom, yellow labels). Note that under conditions of low pre-BCR signaling (*Btk*<sup>-/-</sup>*Slp65*<sup>-/-</sup> pre-B cells) correlation strength is significantly reduced, with the exception of the correlation between de V<sub>κ</sub>3 interaction profiles of the Sis and iEκ elements. (TIF)

**Table S1 Genes down-regulated in the absence of *Btk* and *Slp65*.** (DOC)

**Table S2 Genes up-regulated in the absence of *Btk* and *Slp65*.** (DOC)

**Table S3 Binding of E2a and Ikaros to the κ enhancers and V<sub>κ</sub> genes in wild-type and *Btk* or *Slp65*-deficient pre-B cells.** (DOC)

## Acknowledgments

We thank H. Jumaa (Ulm, Germany), J. Kearney (Birmingham, AL), and C. Murre (San Diego, CA) for kindly providing *Slp65*<sup>-/-</sup>, VH81x transgenic, and *E2a*<sup>-/-</sup> mice, respectively. We thank D. Nemazee (La Jolla, CA) for providing detailed V<sub>κ</sub> usage data. We also thank Z. Özgür, C.E.M. Kockx, Rutger Brouwer, and Mirjam van den Hout (Biomics, Erasmus MC), M. Pescatori (Bioinformatics, Erasmus MC), and P.F. van Loo, I. Bergen, and V. Ta (Pulmonary Medicine, Erasmus MC) for their contributions.

## Author Contributions

The author(s) have made the following declarations about their contributions: Conceived and designed the experiments: RS MVZ ES

FG RWH. Performed the experiments: RS MJWdB MBR CRdA. Analyzed the data: RS RWH MBR SY WvIJ PK. Wrote the paper: RS RWH.
