ABSTRACT

Interleukin (IL)-15 is a pleiotropic cytokine structurally close to IL-2 and sharing with the IL-2R β and γ c receptor (R) subunits. IL-15 plays important roles in innate and adaptative immunity, supporting the activation and proliferation of NK, NK-T, and CD8⁺ T cells. Over-expression of IL-15 has been shown to participate to the development of inflammatory and autoimmune diseases and diverse T cell malignancies. This study is in continuity of our previous work through which a family of small-molecule inhibitors impeding IL-15/IL-2R β interaction with sub-micromolar activity has been identified using pharmacophore-based virtual screening and hit optimization methods. With the aim to improve the efficacy and selectivity of our lead inhibitor, specific modifications have been introduced on the basis of optimized SAR and modelisation. The new series of compounds generated have been evaluated for their capacity to inhibit the proliferation as well as the down-stream signaling of IL-15-dependent cells and to bind to IL-15.

1. INTRODUCTION

Interleukin(IL)-15 is a proinflammatory cytokine, belonging to the IL-2 cytokine family, involved in the stimulation of T and natural killer (NK) cell activity^{1 2}. Dysregulation of IL-15 expression has been described in a range of autoimmune inflammatory diseases, including rheumatoid arthritis, multiple sclerosis, systemic lupus erythematosus, alopecia areata, vitiligo, psoriasis, type 1 diabetes and celiac diseases and in patients with leukemia such as large granular lymphocyte (LGLL), cutaneous T cell lymphoma (CTCL) and human T cell lymphotropic virus I (HTLV-1) driven adult T cell leukemia (ATL).³ IL-15 binds a heterotrimeric receptor composed of a non-transducing, private α chain (IL-15R α) and a IL-2R β / γ c-signal transducing complex.^{4 5} The binding of IL-15 to IL-2R β / γ c heterodimer induces JAK1 activation that subsequently phosphorylates STAT3 (p-Stat3) *via* the IL-2R β chain and JAK3 that subsequently phosphorylates STAT5 (p-Stat5) *via* the γ c chain.^{6 7} Several approaches have been developed to inhibit IL-15 activity, including soluble IL-15R α ⁸, IL-15 mutants⁹, IL-15- or IL-15R-directed monoclonal antibodies and fusion proteins¹⁰, IL-2 mutant or peptide modified to block IL-15 interaction with its receptors (H9-RETR, BNZ-1 and 2)^{11 12} and JAK inhibitors¹³. Smith *et al.* have reported the use of a soluble form of the murine IL-15R α chain (sIL-15R α) to investigate the contribution of IL-15 in the rejection of fully vascularized cardiac allografts in a murine model. Administration of sIL-15R α to CBA/Ca (H-

2k) recipients completely prevented rejection of minor histocompatibility complex-mismatched B10.BR (H-2k) heart grafts and led to a state of donor specific immunologic tolerance¹⁴. In addition, administration of sIL-15R α profoundly suppressed the development of collagen-induced arthritis in mice.⁸ Soluble IL-15R α also prevented psoriasis¹⁵ as well as allergic inflammation¹⁶. In this context, Amgen has developed an anti-IL-15 antibody (AMG-714 or HuMax-IL15) targeting IL-15 in the region involved in γ c chain binding. AMG-714 has first shown efficacy in a xenograft model of human psoriasis and rheumatoid arthritis¹⁷ as well as coeliac disease¹⁸. In psoriasis, it led to a better clinical outcome than the standard cyclosporine A therapy. Likewise, a humanized antibody (Hu-Mik-Beta-1) specific for IL-2R β was developed and was shown to prolong cardiac allograft survival in cynomolgus monkeys.^{19 20 21} This antibody is currently being tested in patients with refractory coeliac disease and HTLV-1-associated tropical spastic paraparesis (HAM/TSP) (clinicaltrials.gov). As an alternative and challenging approach, design of original small molecule inhibitors of protein-protein interactions (PPIs) has recently been applied to target IL-15/IL-15R interfaces. Some potent small-molecule inhibitors of the IL-2/IL-2R α interface have already been identified by chemical or DNA-encoded chemical library screening, fragment-based approaches or virtual library screening followed by chemical optimizations.^{22 23 24 25 26} Concerning IL-15/IL-15R interfaces, a study using *in silico* pharmacophore-based virtual screening methods directed to IL-15/IL-15R α interface has revealed putative IL-15 inhibitors in an *in vitro* primary cellular assay among which cefazolin, a first-generation cephalosporin antibiotic.²⁷ However, it turned that cefazolin was not selective to IL-15 but was rather a broad common gamma chain cytokine inhibitor.²⁸

Meanwhile, using a similar approach coupled to hit optimization, we discovered original low MW non-peptidic inhibitors targeting the IL-15/IL-2R β interface.²⁹ In this previous work, we designed a novel family of IL-15 inhibitors with a thio-triazolyl-methyl-phthalazinone backbone bearing variable alkyl amide fragments. Starting from selected hit derivative **1**, identified through the virtual screening strategy targeting the IL-2R β binding site of IL-15, SAR investigation has given access to a potent lead **2** and other derived analogues showing inhibitory activities against IL-15 with IC₅₀ values ranging between 50 to 150 nM in cell-based experiments (p-Stat5). Unfortunately, none of these IL-15 inhibitors expressed selectivity versus the competitive IL-2.

Based on our docking model (Fig. 1), we proposed to further investigate some options to improve the inhibitory potency of the compounds introducing specific modifications directed

by a modelisation design progress. This process led us to target the triazole or phthalazinone heterocycle cores by substitution of the *N*-Me with *N*-alkylated baits, offering a terminal hydrophilic function, in order to probe complementary hydrogen bond interactions with the polar asparagine side chain residues of the IL-15 protein (Fig. 1B). For this purpose, two novel series of analogues of compounds **1** and **2**, such as *N*-substituted triazole (Fig. 2, Series 1) and phthalazinone (Fig. 2, Series 2) derivatives have been targeted. Furthermore, based on the inhibitor potency of benzamide **2** and its alkoxy or benzoate analogs **2A**, **2B** and **2C**, which gave a good activity in a cell proliferation assay and IC₅₀ at a nanomolar range in a p-Stat5 assay (Fig. 2, Series 3), we proposed to complete our initial series²⁹ with a compound bearing a benzoyl substituent giving also access to a benzophenone derivative which could be regarded as a potential photocrosslinker tool³⁰ (Fig. 2, R₃ modulation).

2. RESULTS AND DISCUSSION

2.1 Chemistry

To access to the first series of *N*-substituted triazole analogues of compounds **1** or **2**, we chose to condense the dihydro-phthalazinone hydrazide **3**²⁹ with an isothiocyanate diethylacetal reagent providing a masked carbonyl group. So, isothiocyanate **4** was condensed with hydrazide **3** to give the *N*-substituted mercapto-triazole derivative **5** in 80% yield. This strategy allowed the access to the desired targeted compounds **10** to **14** from this common precursor (Scheme 1). Both alkylating agents **6** (n = 1) and **7** (n = 7)²⁹ efficiently reacted by nucleophilic

substitution with the thiol **5** in basic conditions, without identification of the *N*-substituted regioisomer. The resulting acetal derivatives **8** and **9** were then subjected to hydrolysis in acidic conditions to yield the corresponding aldehydes **10** and **11**, respectively. The targeted aldehyde **10** with the short linker chain ($n = 1$) was obtained with a good 95 % yield after 2 hours stirring at a temperature of 40 °C. The poor solubility of the acetal **9**, bearing a longer linker chain ($n = 7$), in THF or acetone gave aldehyde **11** in a moderate 59 % yield after completion of the reaction (24 hours). We also observed that in these acidic conditions retro-Michael process occurred leading to the NH free analogue **12**. Intermediate **10** was either reduced with sodium borohydride in an ethanolic medium to furnish the alcohol **13** (67%), or oxidized in Dalcanele conditions³¹ into the corresponding carboxylic acid **14** (60%). However, reduction or oxidation of the aldehyde **11** into the corresponding alcohol or carboxylic acid derivatives was not successful due to poor solubility and slow progress of the reaction in both conditions. Consequently, efficient purification of the reaction products by flash column chromatography failed.

Scheme 1. Synthesis of the *N*-triazolyl propionaldehydes **10** and **11** ($n = 1$ and 7), *N*-triazolyl propanol **13** and *N*-triazolyl propionic acid **14** ($n = 1$).

To access to the targeted *N*-substituted triazolyl analogues of the lead **2** ($n = 7$), we turned back to a linear synthesis starting from hydrazide **3** which was condensed with the isothiocyanate reagents **15**³² and **16**³³ bearing a terminal alcohol or amino function, respectively (Scheme 2). Following this strategy, mercapto-triazole derivatives **17** and **18** were efficiently obtained in 80 % yields and subsequently alkylated with bromo amide fragment **7** leading to the silylated

intermediate **19** and the targeted *N*-dimethylamino propyl analogue **20** in 95% yields. Finally, the alcohol **21** was quantitatively isolated after desilylation of **19** by Olah's reagent prior to be oxidized into the corresponding acid **22** using TEMPO/DAIB system.

Scheme 2. Synthesis of the *N*-triazolyl dimethyl propylamine **20**, *N*-triazolyl propanol **21** and *N*-triazolyl propionic acid **22** compounds (*n* = 7).

The second series of *N*-substituted phthalazinone analogues of compounds **1** or **2** was then investigated. For the short alkyl chain series (*n* = 1), the strategy involved the dihydrophthalazinone carboxylic ester **24**³⁴ quantitatively obtained by the condensation of one equivalent of hydrazine hydrate with the conjugated ester **23** (Scheme 3). Here again a reagent bearing an acetal function regarded as a suitable promoter of a key aldehyde was preliminary introduced on the phthalazinone ring. Thereby, commercial bromo acetal **25** was used to alkylate the phthalazinone prior inducing the formation of the triazol ring in a two steps procedure involving hydrazine hydrate addition followed by a cyclisation with methylisothiocyanate (89 % overall yield). Thioalkylation under Williamson-type conditions in the presence of the bromo amide reagent **6** afforded the key intermediate **28**. Once again, the hydrolysis of the acetal **27** in aqueous HCl medium failed to give aldehyde **29**, however, success was encountered in 81 % yield using APTS (0.5 equiv.) in an acetone/water solvent mixture, at 60 °C overnight. Starting from the aldehyde **29**, both targeted alcohol **30** and carboxylic acid

31 analogues ($n = 1$) were obtained in the same reduction and oxidation conditions, as previously described for the *N*-substituted triazolyl analogues. Alternatively, reductive amination of **29** with dimethylamine in the presence of sodium borohydride also afforded *N*-dimethylaminopropyl analogue **32** conveniently.

Scheme 3. Synthesis of the *N*-phthalazino propionaldehyde **29** and derivatives **30-32** ($n = 1$).

To overcome problems highlighted in precedent attempts, a linear strategy was adopted to reach the targeted *N*-substituted phthalazino compounds bearing heptyl-amido linker ($n = 7$). Starting from the precursor **24**, *N*-alkylation was performed with protected bromopropanol **33**³⁵ or mesylated *N*-dimethylaminopropanol **34**³⁶. Alkylation of **24** monitored by K_2CO_3 as base did not work well and sodium hydride was required to improve the yield of alkylated phthalazinones **35** and **36** to 60 and 75 %, respectively (Scheme 4). The formation of the *N*-methylmercaptotriazole heterocycle was efficient in two steps giving the corresponding thiols **37** (70 %) and **38** (89 %), from **35** and **36**, respectively. Here again the thio-alkylation of thiol **37** and **38** using the bromo reagent **7**, in Williamson-type conditions proceeded smoothly giving

the protected intermediate **39** and the dimethylaminopropyl phthalazinone analogue **40** in moderate 52 and 47 % yields after 24 h of stirring at room temperature. From the protected alcohol derivative **39**, desilylation using Olah's reagent quantitatively led to the targeted *N*-triazolyl propanol compound **41** from which a first oxidation with Dess-Martin periodinane (DMP) reagent afforded the aldehyde analogue **42** and a second oxidation step in Dalcanale conditions gave the carboxylic acid **43**.

To access to the free NH- phthalazinone analogue **46** of the lead compound **2**, a similar strategy was applied starting from compound **23** via the key intermediate **44** obtained in 82 % yield in a refluxing alcoholic solution of hydrazine. The expected analogue **46** was then obtained in 26 % overall yield following a same three steps reaction sequence previously described (Scheme 5). Finally, the targeted benzophenone analogue **49** was quantitatively obtained after alkylation of the intermediate **47**²⁹ with the iodinated amidic chain **48** (Scheme 6).

2.2 Structure-activity analyses

In a previous work, we identified the first IL-15 small molecules inhibitors by a pharmacomodulation study focused on the terminal amidic part of our hit **1** and the linker chain relying it to the triazole-phthalazinone main core of the molecule. Several novel compounds with IC₅₀ values ranging between 50 and 150 nM in cell-based experiments (p-Stat5), were identified and among them a compound **2** (n=7) homolog of the hit **1** (n=1) appeared as the first promising inhibitor candidate. Nevertheless, any of these inhibitors disclosed IL-15 selectivity, displaying the same inhibitory activity on the IL-2 protein. Based on the physicochemical properties of the exposed residues to IL-2Rβ binding site on IL-15 and IL-2 and on the docking of compound **1** to IL-15 (Fig. 1), we have pursued our SAR study towards higher IL-15 inhibitor efficiency and selectivity. Exploring the protein surfaces close to the triazole and phthalazinone moieties of compound **1** (Fig. 1A), we envisioned to graft hydrophilic substituents on chemically modulable nitrogens of both heterocycles. Besides these modifications, we also prepared a benzophenone analogue of compound **2**, in order to complete our previous SAR study²⁹ with a bulky terminal amidic fragment.

The effectiveness of the novel compounds was evaluated using the IL-15- and IL-2-dependent cell proliferation and Stat5 phosphorylation assays and, for some of them, their binding to IL-15 was determined by SPR technology.

2.2.1 In vitro inhibition of cell proliferation and Stat5 phosphorylation

First of all, similar IC_{50} values were retrieved for the reference compounds **1** and **2**, as compared with those previously published²⁹ both in the cell proliferation and p-Stat5 assays (IC_{50} = 22.5 and 4.5 μ M for **1**, respectively and IC_{50} = 2.2 and 0.19 μ M for **2**, respectively), ascertaining the good stability of the two compounds as well as of the two cell lines used (Tables 1 and 2).

In the predicted binding mode of the hit **1** (Fig. 1B), the methyl substituent of the triazole heterocycle was found to share hydrogen bond with the carbamoyl group of the residue asparagine 65 (N65) of IL-15, and the methyl substituent of the phthalazinone moiety seemed to favor hydrophobic interactions with the isoleucine 68 and leucine 69 residues of IL-15. Moreover asparagine residues (Fig 1B, residues N1, N4 and N72) were also pointing in the vicinity of the the phthalazinone moiety. To experimentally sustain the binding mode of this family of inhibitors, we chose to change the *N*-methyl group with hydrophilic substituents sequentially on the triazole or phthalazinone heterocycles to develop two series of analogues of compounds **1** and **2** (Fig. 2, series 1 and series 2, respectively).

The targeted analogues of hit **1** bearing the shorter chain ($n = 1$), uniformly gave no inhibition of cell proliferation (Table 1) as well as p-Stat5 (Table 2). One exception was the *N*-triazolyl substituted analogue **10**, with an aldehyde residue, giving a similar inhibitor potency (IC_{50} values of 6.0 and 4.2 μ M, respectively) than the hit **1**.

As noticed in our previous SAR study,²⁹ some analogues of lead **2** having a longer alkyl chain ($n = 7$), appeared among the most interesting molecules. In these novel series, introduction of an acetal group (compound **9**) on the *N*-substituent of the triazole, a protected or not protected hydroxyl function on either of the heterocycles (compounds **19**, **39** or compounds **21**, **41**) were found deleterious since low or no inhibitory effect was measured either in the cell proliferation and p-Stat5 assays (Tables 1 and 2). Some improvement was observed with the introduction of a carboxylic function as depicted on the triazole analogue **22** (IC_{50} = 9.5 μ M for p-Stat5) but not for the phthalazinone analogue **43** ($IC_{50} > 30$ μ M for p-Stat5). Furthermore, the dimethylaminopropyl residue gave similar results in the cell proliferation assay (IC_{50} = 2-4 μ M) whatever grafted on the triazole (compound **20**) or on the phthalazinone (compound **40**) heterocycles (Table 1) albeit no inhibitory effect of these compounds was detectable in the p-

Stat5 assay (Table 2, $IC_{50} > 30 \mu M$). This discrepancy could reflect a non-specific effect of these compounds affecting the proliferation of the cells independently to Stat5 signaling pathway and consequently of IL-15 or IL-2 stimulation.

As observed with the propionaldehyde derivative **10** in series 1, the analogue **11** with a seven carbons chain appeared as the most efficient inhibitor in this series with its NH-free triazolyl analogue **12**, which gave p-Stat5 inhibition of 280 nM compared to 710 nM for **11**. Because this NH-free triazolyl analogue **12** derived from the propionaldehyde **11** following a retro-Michael process, some doubt remains on the biological stability of the aldehyde **11** and so its efficiency level in these bioassays. At least, compounds **11** and the NH-analogue **12** behaved similarly to compound **2** suggesting the involvement of plausible hydrogen bonds with the carbamoyl function of asparagine N65, as depicted in the binding model (Fig. 1B). Interestingly, in the *N*-substituted phthalazinone series 2, the NH-free analogue **46** appeared absolutely inactive in cell proliferation and Stat5 assays and **42** with the propionaldehyde chain in the range of 10 μM in both bioassays (Tables 1 and 2).

The methyl group on the phthalazinone heterocycle (series 2) of compound **2** seems to have an essential role since its substitution with more polar groups (compounds **39**, **40**, **41**, **43**) or its withdrawal (compound **46**) led to compounds unable to inhibit IL-15-dependent cell proliferation as well as Stat5 phosphorylation (Table 2, $IC_{50} > 30 \mu M$). These results can strengthen the hypothetic binding model which pointed on the interaction of lipophilic residues such as isoleucine 68 and leucine 69 with the *N*-methyl-phthalazinone moiety.

Satisfyingly, data obtained from cell proliferation assays correlate those found in the p-Stat5 assay, highlighting that the proliferative inhibitory effects measured for IL-15 and IL-2 with these analogues resulted from the inhibition of these cytokines signaling pathway. Unfortunately, no selectivity of IL-15 versus IL-2 could be obtained with these novel series of derivatives.

Finally the substitution of the terminal 2,4-dichlorophenyl group of compound **2** with a benzophenone moiety led to the compound **49** which displayed efficiency in the same range of its parent **2** (Tables 1-2, Fig. 3). It can be classified such as the alkoxy analogues **2A** and **2B** or the carboxylate analogue **2C** (Fig.2), among the best representatives of this family with an IC_{50} of 50 nM in the p-Stat5 bioassay with no selectivity observed versus IL-2 ($IC_{50} = 80$ nM). However, such compounds may be of therapeutic interest in pathologies where both cytokines are known to be involved.³⁷

2.2.2 Binding of selected compounds to IL-15.

To complete our study, we focussed on the binding of selected compounds **2**, **11-12**, **41-42**, **46** and **49** to IL-15 using SPR technology. The affinity of these compounds for IL-15 was determined and compared to their pharmacological profile measured in the p-Stat5 assay (Table 3). Thus, recombinant IL-15 was covalently immobilized to sensor chips and the binding at increasing concentrations of the compounds was monitored. Satisfyingly, we could observe that the NH-free phthalazinone compound **46** lacking activity in both cell proliferation and p-Stat5 assays did not bind to IL-15 protein. However, the propanol analogue **41** with similar profile was found to be able to bind to IL-15 with a K_d value of 3.9 μ M. Its behaviour must probably proceed by a different and less specific mode than that of the lead compound **2**, since it was not efficient enough to impair the functional effects of the cytokine.

With the efficient *N*-Me inhibitors such as **2**, the benzophenone analogue **49**, and the NH-triazolyl analogue **12** the protein affinity values were good and closed to 2-3 μM . The compounds bearing an aldehyde function such as **11** and **42**, displayed higher K_d values ($K_d = 5.9$ and 7.8 μM , respectively) in agreement with their IC_{50} values in the p-Stat5 assay. Moreover, these data allow us to confirm that aldehyde **11** is able to bind to the IL-15 protein attesting that the observed biological results (Tables 1 and 2) do not result from its optional metabolite **12**.

3. CONCLUSION

Starting from IL-15 inhibitors identified in our first SAR study and based on docking structural data obtained with our hit **1**, we have developed two novel series of potential IL-15 inhibitors with specific modifications on the *N*-triazole or *N*-phthalazinone heterocycles and we also completed our initial series. Twenty-five compounds have been prepared and tested in two functional bioassays, cell proliferation and p-Stat5 bioassay. In the novel series, the best compounds were found in the *N*-triazole modified family, with the nitrogen substituted with a propionaldehyde chain or free. We also identified a novel benzophenone analogue of our lead compound **2**, with a very good functional activity. These compounds were confirmed as good binders of the targeted protein IL-15. Despite our efforts, we did not succeed in improving IL-15 selectivity in respect with IL-2. However, such inhibitors targeting both IL-15 and IL-2 may be of therapeutic interest in pathologies such as HAM/TSP,¹² CTCL, LGLL and HTLV-1 driven ATL,³ for which these two cytokines have been shown to be involved.

4. EXPERIMENTAL SECTION

4.1 Chemistry.

General. All solvents used were reagent grade and TLC was performed on silica-covered aluminum sheets (Kieselgel 60F254, MERCK). Eluted TLC was revealed using UV radiation ($\lambda = 254$ nm), or molybdate solution. Flash column chromatography was performed on silica gel 60 ACC 40-63 μ m (SDS-CarloErba). NMR spectra were recorded on an Avance I 300 MHz Bruker, on an Avance III 400 MHz Bruker and an Avance III 500 MHz Bruker 500 at room

temperature, on samples dissolved in an appropriate deuterated solvent. References of tetramethylsilane (TMS) for ^1H and deuterated solvent signal for ^{13}C were used. Chemical displacement values (δ) are expressed in parts per million (ppm), and coupling constants (J) in Hertz (Hz). High-Resolution Mass Spectrometry (HRMS in Da unit) analyses were recorded on a Xevo-Q-ToF Waters in the CEISAM Laboratory (AMaCC platform, Nantes) or on a LC-Q-TOF (Synapt-G2 HDMS, Waters) in the IRS-UN center (Mass Spectrometry platform, Nantes).

4.1.1. 1,1-diethoxy-3-isothiocyanatopropane (**4**).

To a solution of 3,3-diethoxypropan-1-amine (1 eq, 11 mmol, 1.78 mL) and anhydrous triethylamine (3.3 eq, 33 mmol, 5 mL) in THF (1.1 mol.L $^{-1}$) at 0 °C under argon atmosphere was added carbon disulfide (1 eq, 11 mmol, 0.66 mL) over a period of 30 min and then stirred at r.t for 2 hours. The mixture was cooled to 0 °C using an ice-bath before tosyl chloride (1.1 eq, 12.1 mmol, 2.3 g) was added in one portion, and the reaction was stirred at r.t for another 30 min. 1N HCl (10 mL) and *t*-butyl methyl ether (MTBE) (10 mL) were added to the mixture. The aqueous layer was extracted with MTBE (10 mL) and the combined organic layers dried over Na $_2$ SO $_4$, filtered and concentrated. The crude oil was purified by flash column chromatography on silica gel (PE/AcOEt, 98:2 to 96:4) to afford the desired product **4** as a colorless oil (9.68 mmol, 1.83 g, 88%). ^1H NMR (300 MHz, CDCl $_3$): δ (ppm) 4.61 (t, 3J = 5.5 Hz, 1H, CH), 3.73-3.46 (m, 6H, NCH $_2$, 2 x OCH $_2$), 2.01-1.93 (m, 2H, CH $_2$), 1.21 (t, 3J = 7.0 Hz, 6H, 2 x CH $_3$). ^{13}C NMR (75MHz, CDCl $_3$): δ (ppm) 130.2 (SCN), 100.2 (CH), 62.4 (OCH $_2$), 41.3 (CH $_2$), 34.2 (CH $_2$), 15.4 (2 x CH $_3$). HRMS (ESI $^+$): calcd for C $_8$ H $_{15}$ NO $_2$ NaS [M+Na] $^+$ m/z 212.0716; found 212.0709.

4.1.2. 4-((4-(3,3-diethoxypropyl)-5-mercapto-4H-1,2,4-triazol-3-yl)methyl)-2-methylphthalazin-1(2H)-one (**5**).

To a suspension of hydrazide **3** (1 eq, 0.82 mmol, 190 mg) in anhydrous ethanol (0.21 mol.L $^{-1}$) at room temperature under argon atmosphere was added isothiocyanate **4** (1 eq, 0.82 mmol, 155 mg) followed by triethylamine (5 eq, 4.1 mmol, 0.57 mL). The mixture was refluxed overnight under argon atmosphere. After completion of the reaction, the mixture was allowed to cool to room temperature, concentrated, and directly purified by flash column chromatography on silica gel (DCM/AcOEt, 50:50) to afford the desired product **5** as a white powder (0.66 mmol, 265 mg, 80%). ^1H NMR (300 MHz, DMSO- d_6): δ (ppm) 13.55 (s, 1H, SH), 8.34-8.26 (m, 1H, H $_{\text{ar-Phthal}}$), 8.05-7.98 (m, 1H, H $_{\text{ar-Phthal}}$), 7.96-7.84 (m, 2H, H $_{\text{ar-Phthal}}$), 4.57 (t, 3J = 5.1 Hz, 1H, CH), 4.52 (s, 2H, CH $_2$), 4.01 (m, 2H, NCH $_2$), 3.67 (s, 3H, NMe), 3.58-3.47 (m, 2H, OCH $_2$), 3.43-3.35 (m, 2H, OCH $_2$), 2.04-1.95 (m, 2H, NCH $_2$ CH $_2$), 1.02 (t, 3J = 7.0 Hz, 6H, 2 x CH $_2$ CH $_3$). ^{13}C NMR (75MHz, DMSO- d_6): δ (ppm) 166.6 (C $_{\text{IV-C=N}}$), 158.4 (CO), 149.3 (C $_{\text{IV-C=N}}$), 140.6 (C $_{\text{IV-C=N}}$), 133.2 (CH $_{\text{ar-Phthal}}$), 132.0 (CH $_{\text{ar-Phthal}}$), 128.8 (C $_{\text{IV}}$), 127.1 (C $_{\text{IV}}$), 126.1 (CH $_{\text{ar-Phthal}}$), 125.6 (CH $_{\text{ar-Phthal}}$), 100.0 (CH), 60.6 (2 x CH $_2$ CH $_3$), 39.6 (NCH $_2$), 38.8 (NMe), 30.7 (NCH $_2$ CH $_2$), 28.8 (CH $_2$), 15.1 (2 x CH $_2$ CH $_3$). HRMS (ESI $^+$): calcd for C $_{19}$ H $_{25}$ N $_5$ NaO $_3$ S [M+Na] $^+$ m/z 426.1570; found 426.1566.

4.1.3. N-(2,4-dichlorophenyl)-2-((4-(3,3-diethoxypropyl)-5-((3-methyl-4-oxo-3,4-dihydrophthalazin-1-yl)methyl)-4H-1,2,4-triazol-3-yl)thio)acetamide (**8**).

To a solution of thiol **5** (1 eq, 0.57 mmol, 230 mg) in DMF (0.06 mol.L⁻¹) under argon atmosphere at room temperature was added K₂CO₃ (1.5 eq, 0.86 mmol, 118 mg) and a solution of α -bromoamide **6** (1.1 eq, 0.63 mmol, 177 mg) in DMF (0.7 mol.L⁻¹) was added. The mixture was then stirred at room temperature for 1 hour until completion. A saturated solution of ammonium chloride was added and the product was extracted twice with AcOEt. The organic layer was washed several times with brine, dried over Na₂SO₄ and concentrated. The crude product was purified by flash column chromatography on silica gel (DCM/MeOH, 98:2) to afford the desired compound **8** as a white powder (0.55 mmol, 318 mg, 96%). ¹H NMR (300 MHz, CDCl₃): δ (ppm) 10.13 (s, 1H, NH), 8.50-8.39 (m, 1H, H_{ar}-Phthal), 8.26-8.15 (m, 2H, H_{ar}-Phthal and H_{ar}), 7.85-7.73 (m, 2H, 2 x H_{ar}-Phthal), 7.30 (d, ⁴J = 2.3 Hz, 1H, H_{ar}), 7.18 (dd, ³J = 8.9 Hz, ⁴J = 2.3 Hz, 1H, H_{ar}), 4.54 (s, 2H, CH₂), 4.50 (t, ³J = 4.8 Hz, 1H, CH), 4.13-4.01 (m, 4H, NCH₂ and SCH₂), 3.80 (s, 3H, NMe), 3.66-3.54 (m, 2H, 2 x OCH₂), 3.49-3.38 (m, 2H, 2 x OCH₂), 2.02-1.88 (m, 2H, NCH₂CH₂), 1.15 (t, ³J = 7.0 Hz, 6H, 2 x CH₃). ¹³C NMR (75MHz, CDCl₃): δ (ppm) 167.3 (CO), 159.5 (CO), 152.9 (C_{IV}-C=N), 151.5 (C_{IV}-C=N), 140.9 (C_{IV}-C=N), 134.0 (C_{IV}), 133.4 (C_{ar}-Phthal), 132.0 (C_{ar}-Phthal), 129.5 (C_{IV}), 129.1 (C_{IV} and C_{ar}), 128.0 (C_{IV}), 127.5 (C_{ar}), 127.3 (C_{ar}-Phthal), 125.2 (C_{ar}-Phthal), 124.8 (C_{IV}), 123.2 (C_{ar}), 100.1 (CH), 62.1 (2 x CH₂), 40.1 (NCH₂), 39.5 (NMe), 36.0 (SCH₂), 33.1 (NCH₂CH₂), 29.9 (CH₂), 15.3 (2 x CH₃). 4.1.4. N-(2,4-dichlorophenyl)-8-((4-(3,3-diethoxypropyl)-5-((3-methyl-4-oxo-3,4-dihydrophthalazin-1-yl)methyl)-4H-1,2,4-triazol-3-yl)thio)octanamide (9).

To a solution of thiol **5** (1 eq, 0.46 mmol, 187 mg) in anhydrous DMF (0.08 mol.L⁻¹) at room temperature under argon atmosphere was added K₂CO₃ (1.5 eq, 0.69 mmol, 95 mg), followed by a solution of bromoamide **7** (1.1 eq, 0.51 mmol, 188 mg) in DMF at 0 °C. The mixture was stirred 4 h at room temperature, quenched with water and extracted with AcOEt. The combined organic layers were washed with brine, dried over MgSO₄, filtered and concentrated under reduced pressure. The product **9** was obtained in quantitative yield without any purification. ¹H NMR (400 MHz, CDCl₃): δ (ppm) 8.43 (dd, ³J = 7.7 Hz, ⁴J = 1.2 Hz, 1H, H_{ar}-Phthal), 8.32 (d, ³J = 8.7 Hz, 1H, H_{ar}), 8.22 (d, ³J = 7.7 Hz, 1H, H_{ar}-Phthal), 7.77 (m, 2H, H_{ar}-Phthal), 7.60 (bs, 1H, NH), 7.36 (d, ³J = 2.35 Hz, 1H, H_{ar}), 7.23 (dd, ³J = 2.35 Hz, ⁴J = 8.88 Hz, 1H, H_{ar}), 4.53 (s, 2H, CH₂), 4.50 (t, ³J = 5.2 Hz, 1H, CH), 4.05 (t, 2H, NCH₂), 3.80 (s, 3H, NMe), 3.61 (m, 2H, 2 x OCH₂), 3.45 (m, 2H, 2 x OCH₂), 3.23 (t, ³J = 7.3 Hz, 2H, SCH₂), 2.40 (t, ³J = 7.30 Hz, 2H, CH₂CO), 1.93 (m, 2H, NCH₂CH₂), 1.72 (m, 4H, 2 x CH₂), 1.37 (m, 6H, 3 x CH₂), 1.17 (t, 6H, 2 x CH₃). ¹³C NMR (100 MHz, CDCl₃): δ (ppm) 171.4 (CO); 159.6 (CO), 151.9 (C_{IV}-C=N), 151.8 (C_{IV}-C=N), 141.1 (C_{IV}-C=N), 133.6 (C_{ar}-Phthal), 133.4 (C_{IV}), 131.9 (C_{ar}-Phthal), 129.2 (C_{IV}), 128.8 (C_{ar}), 128.0 (2 x C_{IV}), 128.0 (C_{ar}), 127.2 (C_{ar}-Phthal), 125.5 (C_{ar}-Phthal), 123.3 (C_{IV}), 122.6 (C_{ar}), 100.2 (CH), 61.9 (2 x OCH₂), 40.1 (NCH₂), 39.5 (NMe), 37.9 (CH₂CO), 33.3 (NCH₂CH₂), 33.1 (SCH₂), 30.0 (CH₂), 29.5 (2 x CH₂), 29.0 (CH₂), 28.8 (CH₂), 28.5 (CH₂), 25.4 (CH₂), 15.4 (2 x CH₃). To a solution of ester **35** (1 eq, 0.98 mmol, 0.4 g) in ethanol (0.2 mol.L⁻¹) at room temperature was added hydrazine monohydrate (6 eq, 6 mmol, 300 μL). The mixture was stirred at 42° C during 24 h then a second portion of hydrazine monohydrate was added (6 eq, 6 mmol, 300 μL) and the mixture was refluxed overnight. After completion of the reaction, the solution was allowed to cool to room temperature and the precipitate was filtered, washed with ethylacetate and dried. The solid hydrazide (0.82 mmol, 0.32 g, 84%) was used in the next step without further purification. ¹H NMR (400 MHz, DMSO-*d*₆): δ(ppm) 9.33 (s, 1H, NH), 8.29-8.27 (m, 1H, CH_{ar}), 7.92-7.83 (m, 3H, CH_{ar}), 4.25 (s, 2H, NH₂), 4.17 (t, J = 7.1 Hz, 2H, NCH₂), 3.78 (s, 2H, CH₂CO), 3.67 (t, J = 6.1 Hz, 2H, CH₂O), 1.93 (m, 2H, CH₂), 0.85 (s, 9H, 3 x CH₃-tBu), 0.02 (s, 6H, 2 x SiCH₃). 4.1.32. 4-((5-mercapto-4-methyl-4H-1,2,4-triazol-3-yl)methyl)phthalazin-1(2H)-one (**45**)

To a suspension of hydrazide **44** (1 eq, 2.2 mmol, 0.5 g) in EtOH were added MeNCS (5 eq, 11.4 mmol, 0.84g), and the mixture was heated at reflux during 3 h. Then DBU (1 eq, 2.2 mmol, 0.35g) was added and heating was maintained during another 3 h. The reaction was cooled to room temperature and the precipitate was filtered and washed with EtOH and Et₂O to afford the desired thiol **45** as a white powder (12.9 mmol, 2.81 g, 69%). ¹H NMR (300 MHz, DMSO-*d*₆): δ(ppm) 13.58 (s, 1H, SH); 12.58 (s, 1H, NH); 8.27 (m, 1H, H_{ar}-Phthal); 8.0-7.85(m, 3H, H_{ar}-Phthal) 4.51(s, 2H, CH₂); 3.42 (s, 3H, CH₃). ¹³C NMR (75 MHz, DMSO-*d*₆): δ(ppm) 166.9 (C_{IV}); 159.3 (C=O); 149.6 (C_{IV}); 140.9 (C_{IV}); 133.6 (CH_{ar}-Phthal); 131.9 (CH_{ar}-Phthal); 129.1 (C_{IV}); 127.6 (C_{IV}); 125.9 (CH_{ar}-Phthal); 125.5 (CH_{ar}-Phthal); 30.1 (CH₃); 28.1 (CH₂). 4.1.33. N-(2,4-dichlorophenyl)-8-((4-methyl-5-((4-oxo-3,4-dihydrophthalazin-1-yl)methyl)-4H-1,2,4-triazol-3-yl)thio)octanamide (**46**)

To a solution of thiol **45** (1 eq, 0.7 mmol, 0.2 g), in dry DMF, bromoamide **7** (1 eq, 0.7 mmol, 0.255 mg) and K₂CO₃ (1.2eq, 0.8 mmol, 0.109 mg) were added. The mixture was then stirred for 48 h, then quenched with a saturated aqueous NH₄Cl solution and extracted with DCM. The organic layer was washed with brine, dried over MgSO₄ and concentrated under reduced pressure. The crude was purified by column chromatography on silica gel (DCM/MeOH, 95:5) to afford the desired product **46** as a white powder (0.34 mmol, 190 mg, 49%). ¹H NMR (300 MHz, DMSO-*d*₆): δ(ppm) 12.55 (s, 1H, NH_{Phthal}); 9.52 (s, 1H, NH); 8.27-8.24 (m, 1H, H_{ar}-Phthal); 8.07-8.04 (m, 1H, H_{ar}); 7.95-7.85(m, 2H, H_{ar}-Phthal); 7.68 (d, *J* = 8.7 Hz, 1H, H_{ar}-Phthal); 7.63 (d, *J* = 2.4 Hz, m, 1H, H_{ar}); 7.6-7.40 (m, 1H, H_{ar}); 4.51 (s, 2H, CH₂); 3.47 (s, 3H, NMe); 3.07 (t, *J* = 7.2 Hz, 2H, SCH₂); 2.36 (t, 2H, *J* = 7.2 Hz, CH₂CO); 1.64-1.54 (m, 4H, 2 x CH₂); 1.35-1.28 (m, 6H, 3 x CH₂). ¹³C NMR (75 MHz, DMSO-*d*₆): δ(ppm) 171.7 (CONH), 159.4 (C=O), 152.7 (C_{IV}-C=N), 151.6 (C_{IV}-C=N), 141.6 (C_{IV}-Phthal), 134.2 (C_{IV}-NHCO), 133.4 (CH_{ar}-Phthal), 131.7 (CH_{ar}-Phthal), 129.2 (C_{IV}), 129.1 (C_{IV}-Cl), 128.8 (CH_{ar}), 128.1 (C_{IV}), 127.7 (CH_{ar}), 127.5 (CH_{ar}-Phthal), 125.9 (CH_{ar}-Phthal), 123.3 (C_{IV}-Cl), 125.6 (CH_{ar}), 39.5 (NMe), 32.5 (CH₂CONH), 30.2 (CH₂S), 29.1 (CH₂), 28.6 (CH₂), 28.4 (CH₂), 28.2 (CH₂), 27.8 (CH₂), 25.0 (CH₂). 4.1.34. N-(4-benzoylphenyl)-8-iodooctanamide (**48**)

To a solution of octanoic acid (1 eq, 1.12 mmol, 250 mg) in DCM (0.11 mmol.mL⁻¹) was added oxalyl chloride (2 eq, 2.24 mmol, 0.197 mL) with some drops of DMF at 0°C. The resulting clear solution was stirred until completion of the reaction. The mixture was concentrated under reduced pressure and a solution of 4-amino benzophenone (1.2 eq, 1.34 mmol, 265 mg), Et₃N (2 eq, 2.24 mmol, 0.312 mL) and DMAP (0.05 eq, 0.056 mmol, 7 mg) in DCM (5 mL) was added slowly and then stirred at room temperature. The mixture was diluted with DCM and washed with water and brine. The organic layer was dried over Na₂SO₄, filtered and concentrated under reduced pressure. The crude was purified by column chromatography on silica gel (DCM/AcOEt, 50:50) to afford the N-(4-benzoylphenyl)-8-bromooctanamide as a white-yellowish solid (0.831 mmol, 327 mg, 74 %). ¹H NMR (300 MHz, CDCl₃): δ (ppm) 7.85 – 7.79 (m, 2H, 2 x CH_{ar}), 7.79 – 7.71 (m, 2H, 2 x CH_{ar}), 7.68 – 7.62 (m, 2H, 2 x CH_{ar}), 7.62 – 7.53 (m, 1H, CH_{ar}), 7.53 – 7.44 (m, 2H, 2 x CH_{ar}), 7.39 (s, 1H, NH), 3.41 (t, *J* = 6.8 Hz, 2H, CH₂-Br), 2.51 – 2.35 (m, 2H, CH₂-CONH), 1.92 – 1.81 (m, 2H, CH₂), 1.81 – 1.66 (m, 2H, CH₂), 1.49 – 1.37 (m, 6H, 3 x CH₂). HRMS (ESI⁺): calcd for C₂₁H₂₅NO₂Br [M+H]⁺ *m/z* 402.1059;

found 402.1069. NaI (2.25 eq, 14.54 mmol, 2.18 g) was added to a solution of bromo compound previously obtained (1 eq, 6.46 mmol, 2.60 g) in acetone (0.7 mol.L⁻¹). The solution was allowed to reflux during 2 h then concentrated. The residue was solubilized in DCM and NaI/NaBr salts were filtered off. The organic layer was then concentrated under reduced pressure to afford the expected iodo compound **48** as a yellow viscous oil (6.45 mmol, 2.90 g, quant.). ¹H NMR (300 MHz, CDCl₃): δ (ppm) 8.30 (s, 1H, NH), 7.81 – 7.72 (m, 4H, 4 x CH_{ar}-CO), 7.68 (d, *J* = 8.8 Hz, 2H, 2 x CH_{ar}), 7.61 – 7.52 (m, 1H, CH_{ar}), 7.50 – 7.37 (m, 2H, 2 x CH_{ar}), 3.14 (t, *J* = 7.0 Hz, 2H, CH₂-I), 2.38 (t, *J* = 7.5 Hz, 2H, CH₂-CONH), 1.82 – 1.73 (m, 2H, CH₂), 1.70 (m, 2H, CH₂), 1.34 (m 6H, 3 x CH₂). ¹³C NMR (75 MHz, CDCl₃): δ (ppm) 196.1 (C=O), 172.2 (CONH), 142.5 (C_{IV}-NHCO), 137.8 (C_{IV}-CO), 132.7 (C_{IV}-CO), 132.4 (CH_{ar}), 131.7 (2 x CH_{ar}), 129.9 (2 x CH_{ar}), 128.4 (2 x CH_{ar}), 118.9 (2 x CH_{ar}), 37.7 (CH₂-CONH), 33.4 (CH₂), 30.3 (CH₂), 29.1 (CH₂), 28.3 (CH₂), 25.4 (CH₂), 7.3 (CH₂-I). 4.2 Biological assays

4.2.1 Cell lines, recombinant proteins and antibodies. The 32Dβ and NK-92 cell lines were used in that study and cultured as described previously^{37 38}. Recombinant human IL-15, recombinant murine IL-3 were obtained from Peprotech, Inc. and recombinant human IL-2 from Chiron. RLI, an IL-15 agonist was produced as described previously³⁹.

4.2.2 Proliferation assays. The proliferation response of 32D β cells to RLI,³⁹ was assessed by Alamar blue reduction assay (AbDSerotec). Cells were starved in the culture medium without cytokine for 4 h. Cells (1×10^4) were cultured for 2.5 days in the medium supplemented with 100 pM RLI or 1.5 nM IL-2, previously preincubated for 30 min with increasing concentrations of compounds. Cell proliferation was revealed by adding Alamar blue (10 μ l) to each well and, after a 6h-incubation period at 37 °C, by measuring the emitted fluorescence at 590 nm under excitation at 560 nm using an EnSpire Multimode Plate Reader (Perkin Elmer)

4.2.3 P-Stat5 assays. Exponentially-growing NK-92 cells were washed and serum-starved overnight to reduce basal phosphorylation. Cells (2×10^5) were then stimulated at 37 °C for 1 h with fixed concentrations of IL-15 or IL-2 that have been preincubated for 30 min with increasing concentrations of chemical compounds. At the end of the stimulation, cells were lysed and Stat5 phosphorylation was measured according to the manufacturer's instructions using p-Stat5 AlphaScreen Surefire kit (Perkin Elmer Life Sciences). The signal in the wells was then detected using an EnSpire Multimode Plate Reader (Perkin Elmer).

4.2.4 SPR experiment. The SPR experiments were performed at 25°C on a Biacore T200 biosensor (GE Healthcare, Chalfont St Giles, UK). Recombinant IL-15 was covalently immobilized to CM5 sensor chips using the amine coupling method in accordance with the manufacturer's instructions, and the binding of compounds at increasing concentrations, prepared in HBSEP/DMSO (0.1 %) was monitored. The Biacore T200 Evaluation 3.0 software (GE Healthcare) was used to run experiments and for data analysis.
