## In Brief

Fahl et al. reveal a regulatory axis where T cell receptor (TCR) signaling controls TCF1 expression through an E-protein-bound regulatory element, and this regulatory axis modulates  $\gamma\delta$  lineage commitment and effector fate. This finding provides mechanistic insight into how TCR signals promote adoption of the  $\gamma\delta 17$  effector fate.

## Highlights

- TCF1 expression levels regulate  $\gamma\delta$  lineage commitment and effector function
- TCF1 expression in developing  $\gamma\delta$  T cells is controlled by TCR induction of Id3
- Id3 induction represses TCF1 by blocking E protein binding to an intronic element
- This regulatory element controls TCF1 expression in  $\gamma\delta$  but not  $\alpha\beta$  precursors

## SUMMARY

TCF1 plays a critical role in T lineage commitment and the development of  $\alpha\beta$  lineage T cells, but its role in  $\gamma\delta$  T cell development remains poorly understood. Here, we reveal a regulatory axis where T cell receptor (TCR) signaling controls TCF1 expression through an E-protein-bound regulatory element in the *Tcf7* locus, and this axis regulates both  $\gamma\delta$  T lineage commitment and effector fate. Indeed, the level of TCF1 expression plays an important role in setting the threshold for  $\gamma\delta$  T lineage commitment and modulates the ability of TCR signaling to influence effector fate adoption by  $\gamma\delta$  T lineage progenitors. This finding provides mechanistic insight into how TCR-mediated repression of E proteins promotes the development of  $\gamma\delta$  T cells and their adoption of the interleukin (IL)-17-producing effector fate. IL-17-producing  $\gamma\delta$  T cells have been implicated in cancer progression and in the pathogenesis of psoriasis and multiple sclerosis.

## INTRODUCTION

$\gamma\delta$  lineage T cells play a critical role in host defense that is at least partially distinct from that of  $\alpha\beta$  T cells (Chien et al., 2014; Nielsen et al., 2017; Vantourout and Hayday, 2013). Both of these T cell lineages arise from a common CD4<sup>−</sup>CD8<sup>−</sup> (double-negative; DN) progenitor pool in the thymus (Ciofani et al., 2006; Petrie et al., 1992). A critical factor instructing separation of these lineages is the nature of T cell receptor (TCR) signals experienced by immature progenitors, with weak and strong TCR signals promoting the adoption of the  $\alpha\beta$  and  $\gamma\delta$  T cell fates, respectively (Haks et al., 2005; Hayes et al., 2005). The signaling cascade that is differentially induced to specify these alternative lineage fates comprises the activation of tyrosine kinases, mitogen-activated protein kinases (MAPKs), early growth response (Egr) transcription factors (TFs), and inhibitor of DNA binding (Id) family members (Id2 and Id3) (Lauritsen et al., 2009; Ueda-Hayakawa et al., 2009; Zhang et al., 2014). The TCR-mediated induction of Id proteins then represses the activity of E box DNA-binding proteins (E proteins) in a graded manner in proportion to TCR signal strength (Bain et al., 2001; Lauritsen et al., 2009). However, the critical E protein targets differentially affected by these distinct fate-determining signals remain to be identified.

In addition to commitment to the  $\gamma\delta$  T cell lineage, the effector fate of most  $\gamma\delta$  T cells—either interferon- $\gamma$  (IFN- $\gamma$ ) or interleukin (IL)-17 production—is also determined in the thymus (Jensen and Chien, 2009; Muñoz-Ruiz et al., 2017; Prinz et al., 2013; Vantourout and Hayday, 2013; Wiest, 2016). The molecular events controlling the specification of  $\gamma\delta$  T cell effector fate remain controversial, specifically regarding the relative importance of developmental context versus TCR signaling. While there are reports indicating that TCR-independent developmental context impacts the potential of a precursor to adopt the IL-17-producing effector fate (Haas et al., 2012; Spidale et al., 2018), there is substantial, widely accepted evidence that TCR signaling plays a key role in the intrathymic generation of functional  $\gamma\delta$  T cell effectors. Indeed, strong  $\gamma\delta$ TCR signals are thought to be required for the development of IFN- $\gamma$ -producing  $\gamma\delta$  T cells, while IL-17-producing fate is thought to be incompatible with strong  $\gamma\delta$ TCR signals, instead requiring weak TCR signals (Fahl et al., 2018; Jensen et al., 2008; Muñoz-Ruiz et al., 2016; Sumaria et al., 2017). The signals of differing intensity that lead to the adoption of these effector fates have been linked to the TF, whose function is important for the particular effector fate. Specifically, IFN- $\gamma$  producers depend on the function of Egr3, which is induced by strong TCR signals, while IL-17 producers

depend on the actions of ROR $\gamma$ t, SOX13, and c-MAF (Gray et al., 2013; Malhotra et al., 2013; Turchinovich and Hayday, 2011; Zuberbuehler et al., 2019). Nevertheless, accumulating evidence suggests that the paradigm of strong and weak TCR signals promoting the IFN- $\gamma$ - and IL-17-producing effector fates, respectively, may be too simplistic. Indeed, unlike the IL-17 producers that develop in response to weak signals in the absence of ligand, the Hayday laboratory reported that some IL-17-producing  $\gamma\delta$  T cells are dependent on strong TCR signals, as evidenced by the impairment of their development by attenuation of TCR signaling (Wencker et al., 2014). ROR $\gamma$ t and SOX13, along with Sox4, have been implicated in the development of this population of innate-like IL-17-producing  $\gamma\delta$  T cells (Gray et al., 2013; Wencker et al., 2014), which show limited capacity to produce IL-17 in response to TCR engagement but exhibit robust production of IL-17 in response to cytokine stimulation (IL-1 and IL-23) (Wencker et al., 2014). Although this report is seemingly at odds with several other studies indicating that the IL-17 fate is incompatible with strong TCR signals (Fahl et al., 2018; Jensen et al., 2008; Muñoz-Ruiz et al., 2016; Sumaria et al., 2017), two recent reports provide a potential explanation for this apparent discrepancy (In et al., 2017; Zuberbuehler et al., 2019). The Ciofani laboratory determined that the TF c-Maf is required for the development of IL-17-producing  $\gamma\delta$  T cells and determined that c-Maf induction was inversely associated with  $\gamma\delta$ TCR signal strength, as defined by CD5 induction (Zuberbuehler et al., 2019); however, c-Maf is also robustly induced by ectopic expression of activated mutants of the signaling molecules protein kinase C (PKC) and Ras (Zuberbuehler et al., 2019). Ectopic expression of these activated signaling molecules could not reasonably be described as generating weak signals but might rather be regarded as producing distinct signals, compatible with c-Maf induction. Another study from the Anderson laboratory suggests that there are two distinct developmental pathways for IL-17-producing  $\gamma\delta$  T cells, and these pathways are distinguished by CD73 expression (In et al., 2017). CD73 expression, which is induced by  $\gamma\delta$ TCR-ligand engagement and strong TCR signals, marks the commitment of most  $\gamma\delta$  precursors to the  $\gamma\delta$  lineage (Coffey et al., 2014; In et al., 2017); however, some IL-17-producing  $\gamma\delta$  T cells do not pass through a CD73+ stage, consistent with their adoption of the IL-17-producing effector fate in response to weaker or distinct TCR signals (In et al., 2017). Taken together, these data suggest that there are two pathways of IL-17  $\gamma\delta$  T cell development, one that is compatible with stronger, ligand-induced  $\gamma\delta$ TCR signals and another driven by a weaker, or perhaps distinct, constellation of signals.

The molecular link between the  $\gamma\delta$ TCR signals that promote development of IL-17-producing  $\gamma\delta$  T cells and the TFs responsible for orchestrating the IL-17-producing differentiation program, HEB, c-Maf, Sox4, and Sox13, remains unclear (Gray et al., 2013; In et al., 2017; Malhotra et al., 2013; Turchinovich and Hayday, 2011; Zuberbuehler et al., 2019). Analysis of the molecular mechanism through which these TFs orchestrate the development of IL-17-producing  $\gamma\delta$  cells has centered primarily on their capacity to regulate expression of the critical TF, ROR $\gamma$ t (Malhotra et al., 2013; Zuberbuehler et al., 2019). The capacity of Sox4, Sox13, and c-Maf to promote ROR $\gamma$ t expression is antag-

onized by the action of TCF1 (Malhotra et al., 2013; Zuberbuehler et al., 2019). TCF1 is a high-mobility group (HMG) box TF that has been demonstrated to play an important role in the Notch-mediated commitment of thymic progenitors to the T cell fate (Germar et al., 2011; Weber et al., 2011). It does so by remodeling the epigenetic landscape and transactivating the expression of gene targets critical for the commitment and development of  $\alpha\beta$  T cell progenitors (Emmanuel et al., 2018; Goux et al., 2005; Johnson et al., 2018); however, TCF1 loss was not reported to adversely affect fetal  $\gamma\delta$  T cell development (Okamura et al., 1998). TCF1 function has been reported to antagonize the development of IL-17-producing  $\gamma\delta$  T cells (Malhotra et al., 2013). Accordingly, the development of IL-17-producing  $\gamma\delta$  T cells appears to be controlled by the antagonistic balance of the positive regulatory action of Sox14, Sox13, and c-Maf versus the negative regulation of TCF1. The mechanism by which this balance is set and influenced by TCR signaling remains a critical unanswered question.

Here, we report that TCF1 plays a critical role not only in regulating  $\gamma\delta$  T cell effector function but also in  $\gamma\delta$  T lineage commitment. Importantly, the negative regulatory effect of TCF1 is mitigated by  $\gamma\delta$ TCR signals, which repress TCF1 expression during  $\gamma\delta$  T lineage commitment and maturation. TCR signals do so through a regulatory E-protein-bound element (EPE) located in the first intron of the *Tcf7* locus. Collectively, these data suggest that TCR signals promote adoption of the  $\gamma\delta$  T cell fate and tip the regulatory balance in favor of the positive regulators of IL-17 effector function, do so by attenuating the expression of the antagonist TF, TCF1.

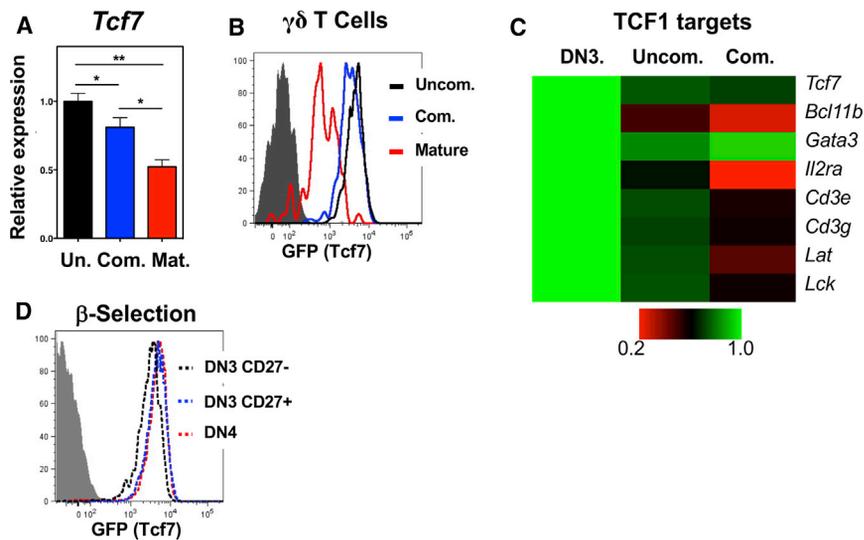

## RESULTS

### TCF1 expression levels are reduced during $\gamma\delta$ T cell development

The contribution of TCF1 to separation of the  $\alpha\beta$  and  $\gamma\delta$  T cell fates has not been explored. Quantitative PCR (qPCR) analysis revealed that levels of mRNA encoding TCF1 (*Tcf7*) decreased as adult bipotential,  $\gamma\delta$  TCR-expressing cells (CD24<sup>+</sup>CD73<sup>-</sup>; uncommitted [Uncom.] commit to the  $\gamma\delta$  lineage (CD24<sup>+</sup>CD73<sup>+</sup>; committed [Com.]) and mature (CD24<sup>-</sup>CD73<sup>+</sup>mature [Mat.]) (Figure 1A; Coffey et al., 2014). Similar changes in *Tcf7* expression were also observed using a *Tcf7* reporter (Figure 1B) (Xu et al., 2017) and by intracellular staining (Figure S1A). *Tcf7* expression also declined during differentiation of fetal progenitors into committed  $\gamma\delta$  lineage cells, and this was accompanied by reduced expression of its target genes, including *Bcl11b* (Figure 1C). Interestingly, *Tcf7* expression was not reduced in  $\alpha\beta$  lineage cells, as they traversed the  $\beta$ -selection checkpoint and differentiated to the CD4<sup>-</sup>CD8<sup>-</sup>CD44<sup>-</sup>CD25<sup>-</sup>DN4 stage (Figures 1D and S1A), indicating that the reduction in expression is restricted to  $\gamma\delta$  T cell development. Taken together, these data indicate that *Tcf7* levels are selectively downmodulated during  $\gamma\delta$  T cell development.

### TCF1 deficiency markedly alters $\gamma\delta$ T cell development

To determine whether the reduction in *Tcf7* expression that occurs during  $\gamma\delta$  T cell development plays an important role in regulating  $\gamma\delta$  lineage commitment and effector fate, we analyzed

**Figure 1. *Tcf7* expression decreases during  $\gamma\delta$  T cell development**

(A) Quantitative real-time PCR analysis of *Tcf7* mRNA on electronically sorted adult  $\text{Thy1}^+ \text{CD4}^- \text{CD8}^- \text{TCR}\delta^+ \text{CD24}^+ \text{CD73}^-$  (uncommitted [Uncom.]),  $\text{CD24}^+ \text{CD73}^+$  ( $\gamma\delta$  lineage committed [Com.]), and  $\text{CD24}^- \text{CD73}^+$  (mature [Mat.])  $\gamma\delta$  T cell subsets. mRNA levels were normalized to the expression of *Gapdh*. Data are representative of three independent experiments. p values were calculated from triplicate measurements within each experiment. Error bars represent  $\pm$  SD. \* $p < 0.05$ ; \*\* $p < 0.005$ .

(B)  $\gamma\delta$  developmental intermediates from adult *Tcf7*<sup>GFP/+</sup> mice were analyzed for GFP expression:  $\text{Thy1}^+ \text{CD4}^- \text{CD8}^- \text{TCR}\delta^+ \text{CD24}^+ \text{CD73}^-$  (Uncom.),  $\text{CD24}^+ \text{CD73}^+$  (Com.), and  $\text{CD24}^- \text{CD73}^+$  (Mat.) cells.

(C) Heatmap depicting TCF1 target genes in fetal DN3,  $\gamma\delta\text{TCR}^+ \text{CD24}^+ \text{CD73}^-$  (Uncom.), and  $\gamma\delta\text{TCR}^+ \text{CD24}^+ \text{CD73}^+$  (Com.). RNA-seq was performed on fetal liver progenitor-derived *Rag2*<sup>-/-</sup> DN3 cells and KN6  $\gamma\delta\text{TCR}$ -transduced *Rag2*<sup>-/-</sup>

DN3 cells and KN6  $\gamma\delta\text{TCR}$ -transduced *Rag2*<sup>-/-</sup> DN3 cells (two independent replicates each). Data are reads per kilobase million (RPKM) values for each gene and are normalized to the RPKM values in DN3 cells.

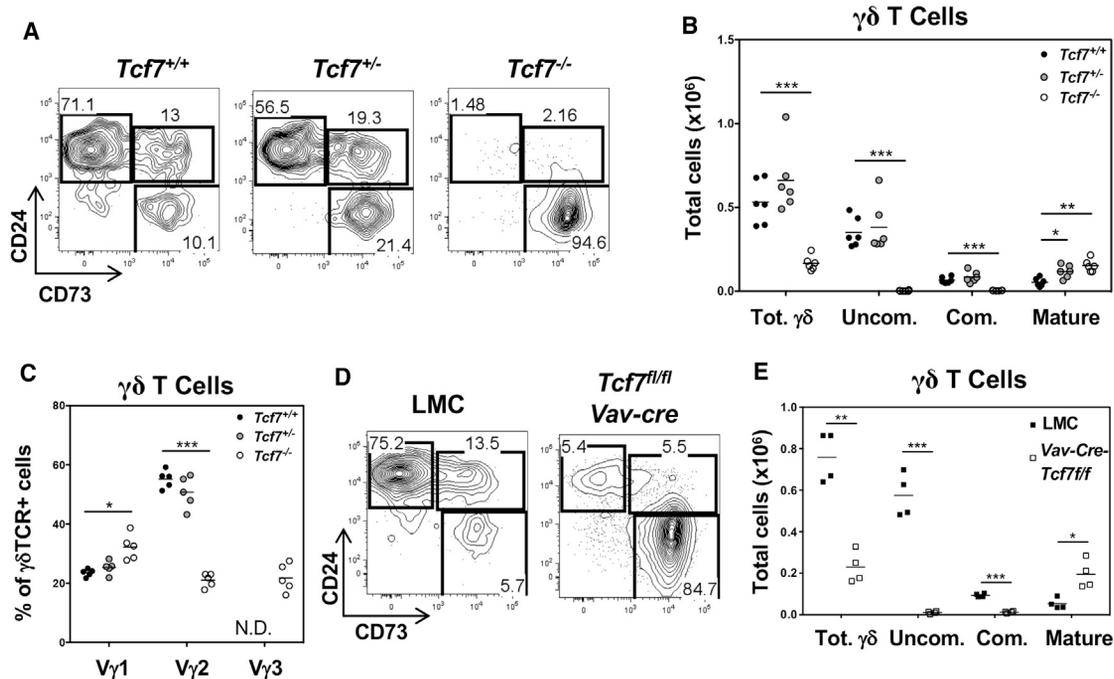

(D) Thymocytes from *Tcf7*<sup>GFP/+</sup> mice were analyzed for GFP expression in  $\text{Thy1}^+ \text{CD4}^- \text{CD8}^- \text{TCR}\delta^- \text{CD44}^- \text{CD25}^+ \text{CD27}^-$  (CD27<sup>-</sup> DN3),  $\text{CD25}^+ \text{CD27}^+$  (CD27<sup>+</sup> DN3), and  $\text{CD25}^-$  (DN4) cells. Gray shaded histogram represents GFP expression in  $\text{Thy1}^+ \text{CD4}^- \text{CD8}^- \text{TCR}\delta^+$  thymocytes from *Tcf7*<sup>+/+</sup> mice.  $n = 4$  mice.

development in TCF1-deficient (*Tcf7*<sup>-/-</sup>) mice. Indeed, TCF1 deficiency markedly altered  $\gamma\delta$  T cell development in the thymus. The total number of  $\gamma\delta$  T cells was significantly reduced in TCF1-deficient thymi, owing largely to the loss of  $\text{CD24}^+ \text{CD73}^-$  uncommitted and  $\text{CD24}^+ \text{CD73}^+$  committed  $\gamma\delta$  T cell progenitors (Figures 2A and 2B). Importantly, the number of mature  $\gamma\delta$  T cells was markedly increased, relative to that in controls, in both proportion and number (Figures 2A and 2B). Similar changes in these subsets were already evident in neonates, where the total number of  $\gamma\delta$  T cells was unchanged, but there was a marked skewing toward committed and mature  $\gamma\delta$  T cells (Figures S1B–S1E). Mature  $\gamma\delta$  T cell proportion and number were also increased in adult *Tcf7*<sup>+/-</sup> mice, although the effect was not as pronounced as in *Tcf7*<sup>-/-</sup> mice (Figures 2A and 2B). The representation of particular V $\gamma$  subsets was altered by TCF1 deficiency. The V $\gamma$ 1 and V $\gamma$ 2 subsets were increased and decreased, respectively, while representation of the V $\gamma$ 4 and V $\gamma$ 5 subsets was unchanged (Figures 2C and S2A). Interestingly, the V $\gamma$ 3 subset, which is generated in the first fetal wave of development, migrates to the skin and is never observed in adult thymus; however, the V $\gamma$ 3<sup>+</sup> cells were markedly increased in the thymi of TCF1-deficient adult mice, where their abundance was on par with that of the V $\gamma$ 1<sup>+</sup> and V $\gamma$ 2<sup>+</sup> subsets (Figure 2C). V $\gamma$ 3 cells were depleted from the skin, raising the possibility that their presence in the thymus resulted from a failure to exit the thymus (Figures S2B and S2C). Consistent with this possibility, expression of the chemokine receptor required for skin migration, *Ccr10* (Xia et al., 2010), was reduced in  $\gamma\delta$  T cells from TCF1-deficient mice (Figure S2D). The effects of TCF1 deficiency are entirely cell-autonomous, as they were reproduced upon conditional ablation of *Tcf7* during fetal development of hematopoietic progenitors using Vav-Cre (Figures 2D, 2E, and S3A) (de Boer et al., 2003). Notably, when *Tcf7* ablation was mediated

by CD2-Cre, after progenitors have entered the thymus, the skewing toward mature ( $\text{CD73}^+ \text{CD24}^-$ )  $\gamma\delta$  T cell populations is also evident but is not associated with loss of immature  $\gamma\delta$  T cell progenitors, indicating that their absence upon Vav-Cre or germline ablation of *Tcf7* likely results from loss of TCF1 support for the early phases of T lineage commitment (Figures S3B and S3C) (Germar et al., 2011; Weber et al., 2011). Co-deletion of both members of the TCF/LEF family of transcriptional regulators, *Tcf7* and *Lef1*, using CD2-Cre, exacerbated the skewing toward mature  $\gamma\delta$  T cell populations, suggesting that LEF1 partially compensates for TCF1 deficiency (Figures S3B and S3C). The effect of TCF1/LEF1 double deficiency was most prominent among V $\gamma$ 2<sup>+</sup>  $\gamma\delta$  T cells and those lacking both V $\gamma$ 1 and V $\gamma$ 2 (Figure S3C). Taken together, these data demonstrate that TCF1 deficiency alters  $\gamma\delta$  T cell development, suggesting that the expression level of TCF1 plays a critical role in this process.

### TCF1 expression levels influence T cell fate

The capacity of TCF1 deficiency to cause cell-autonomous increases in committed and mature  $\gamma\delta$  lineage T cells raised the possibility that TCF1 might regulate  $\gamma\delta$  lineage commitment. To test this possibility, we used the KN6  $\gamma\delta\text{TCR}$  transgenic (Tg) mouse model, where fate specification can be controlled by manipulating access to ligand (Pereira et al., 1992). When KN6  $\gamma\delta$  T lineage progenitors encounter the H2-T22<sup>d</sup> ligand, they adopt the  $\gamma\delta$  fate and mature into IFN- $\gamma$ -producing  $\gamma\delta$  T cells; however, upon removal of ligand, this same  $\gamma\delta\text{TCR}$  redirects progenitors to adopt the  $\alpha\beta$  T cell fate and differentiate to the  $\text{CD4}^+ \text{CD8}^+$  double-positive (DP) stage (Fahl et al., 2018). Consequently, we sought to determine whether short hairpin RNA (shRNA)-mediated knockdown of TCF1 expression enhanced the capacity of  $\gamma\delta$  T lineage progenitors to adopt the  $\gamma\delta$  fate, even under suboptimal TCR signaling conditions, produced by

**Figure 2. TCF1 deficiency alters  $\gamma\delta$  T cell development**

(A) Thymocytes from *Tcf7*<sup>+/+</sup>, *Tcf7*<sup>+/-</sup>, and *Tcf7*<sup>-/-</sup> mice were analyzed for surface expression of Thy1, CD4, CD8, TCR $\delta$ , CD24, and CD73. Flow plots depict subsets defined by CD24 and CD73 that were pre-gated on Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> cells.

(B) Absolute numbers of total  $\gamma\delta$  (Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup>), uncommitted  $\gamma\delta$  (Uncom.; Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> CD24<sup>+</sup> CD73<sup>-</sup>), committed  $\gamma\delta$  (Com.; Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> CD24<sup>+</sup> CD73<sup>+</sup>), and mature  $\gamma\delta$  (Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> CD24<sup>-</sup> CD73<sup>+</sup>) T cells in the thymus of *Tcf7*<sup>+/+</sup>, *Tcf7*<sup>+/-</sup>, and *Tcf7*<sup>-/-</sup> mice were calculated from gate frequencies.

(C) Percentage of Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> V $\gamma$ 1<sup>+</sup>, V $\gamma$ 2<sup>+</sup>, and V $\gamma$ 3<sup>+</sup>  $\gamma\delta$  T cells in the thymus of *Tcf7*<sup>+/+</sup>, *Tcf7*<sup>+/-</sup>, and *Tcf7*<sup>-/-</sup> mice. N.D., not detected.

(D) Thymocytes from *Tcf7*<sup>fl/fl</sup> *Vav-cre* mice and littermate controls (LMCs) were analyzed for surface expression of Thy1, CD4, CD8, TCR $\delta$ , CD24, and CD73. Flow plots displaying populations defined by CD24 and CD73 expression were pre-gated on Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> cells.

(E) Absolute numbers of total  $\gamma\delta$ , uncommitted  $\gamma\delta$  (Uncom.), committed  $\gamma\delta$  (Com.), and Mat.  $\gamma\delta$  T cells in the thymus of *Tcf7*<sup>fl/fl</sup> *Vav-cre* mice, and LMCs were quantified from gate frequencies and are depicted as scatterplots.

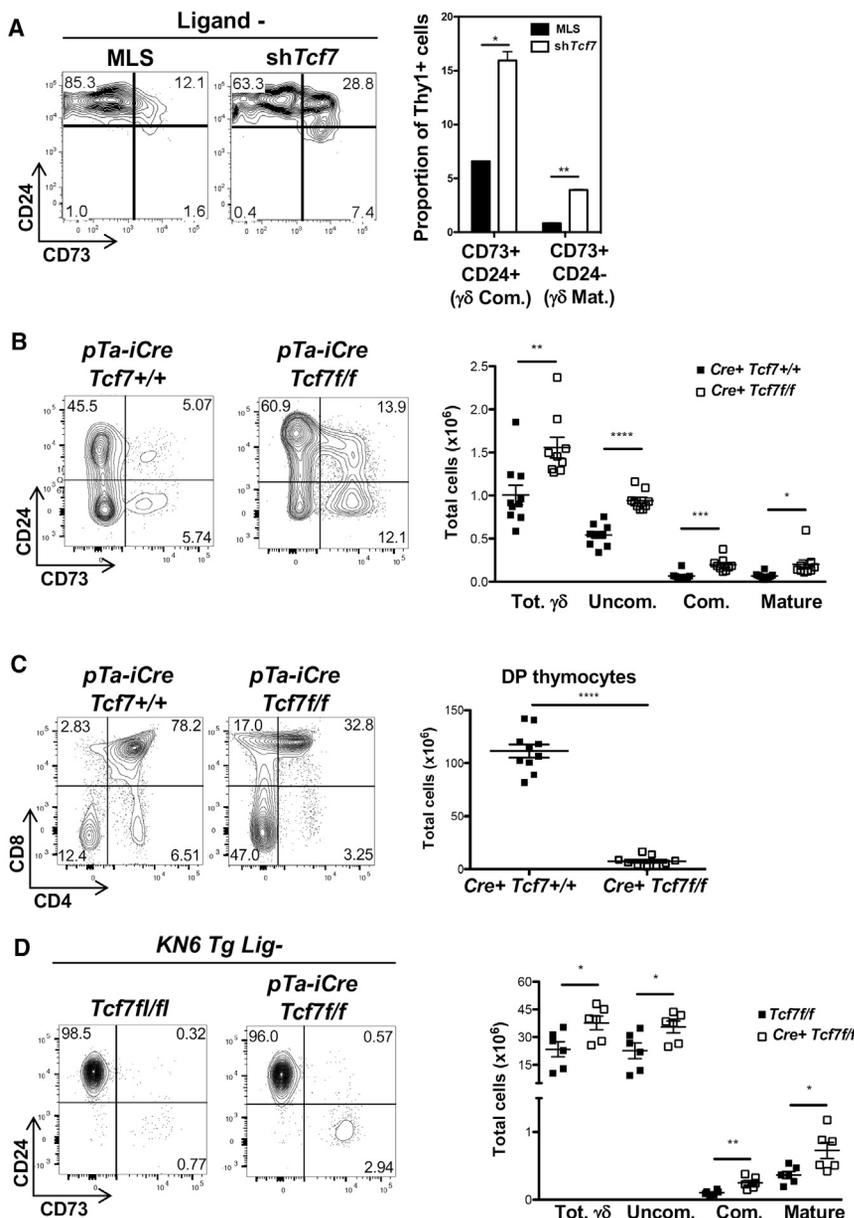

n = 6 mice (A and B), 5 mice (C), and 4 mice (D and E) per genotype. Each point represents an individual mouse. \*p < 0.01; \*\*p < 0.001; \*\*\*p < 0.0001.

limiting access to ligand. Indeed, KN6  $\gamma\delta$ TCR-expressing progenitors that had been transduced with *Tcf7* shRNA displayed a profound increase in the proportion of progenitors that committed to the  $\gamma\delta$  lineage (CD24<sup>+</sup>CD73<sup>+</sup> and CD24<sup>-</sup>CD73<sup>+</sup>) relative to control (Figures 3A, S4A, and S4B). However, because TCF1 knockdown impairs the development of early progenitors, the absolute number of committed  $\gamma\delta$  T lineage progenitors was not increased (data not shown). To eliminate the effect of TCF1 loss on early T lineage progenitors, we used pT $\alpha$ -iCre-mediated ablation of *Tcf7*, since this occurs after the initial steps of T lineage commitment (Luche et al., 2013). Interestingly, pT $\alpha$ -iCre-mediated marking of progenitors using a lox-stop-lox ZsGreen (LSL-ZsG) allele revealed few CD73<sup>+</sup>, committed  $\gamma\delta$  T lineage T cells; however, pT $\alpha$ -iCre-mediated ablation of *Tcf7* markedly increased both the proportion and number of committed and mature  $\gamma\delta$  T lineage T cells, while simultaneously reducing the number of  $\alpha\beta$ -lineage CD4<sup>+</sup>CD8<sup>+</sup> DP thymocytes (Figures 3B and 3C). The increase in committed and mature  $\gamma\delta$  T lineage T cells was not associated with increased proliferation (Figure S4C). This suggests that, in addition to its role in facilitating T lineage commitment, TCF1 also influences the subsequent step of  $\alpha\beta/\gamma\delta$  lineage commitment. To directly test this *in vivo*,

we used pT $\alpha$ -iCre ablation of *Tcf7* in the KN6 model to determine whether TCF1 loss promoted  $\gamma\delta$  lineage commitment even when TCR signaling was severely attenuated by the absence of ligand. Indeed, TCF1 deficiency increased the proportion and number of KN6 Tg T lineage progenitors that induced CD73 expression and adopted the  $\gamma\delta$  T lineage, despite being deprived of TCR ligand stimulation (Lig<sup>-</sup>; Figure 3D). Taken together, these data suggest that, in addition to its ability to promote T lineage commitment, TCF1 also plays a subsequent role in the separation of the  $\alpha\beta$  and  $\gamma\delta$  T lineages, with reduced TCF1 expression facilitating adoption of the  $\gamma\delta$  T cell fate.

### TCF1 deficiency disrupts the specification of effector fate

TCF1 deficiency has previously been implicated in the regulation of  $\gamma\delta$  T cell effector fate in conjunction with signals involving the Wnt/ $\beta$ -catenin pathway (Malhotra et al., 2013). To investigate this possibility, we evaluated the impact of TCF1 deficiency on the generation of the CD27/NK1.1 phenotypes of  $\gamma\delta$  T cells linked to distinct effector fates (Ribot et al., 2009). We found that TCF1 deficiency markedly diminished the CD27<sup>+</sup> IFN- $\gamma$ -producing effectors while markedly increasing the CD27<sup>-</sup> subset linked to

**Figure 3. TCF1 insufficiency alters  $\gamma\delta$  T cell selection**

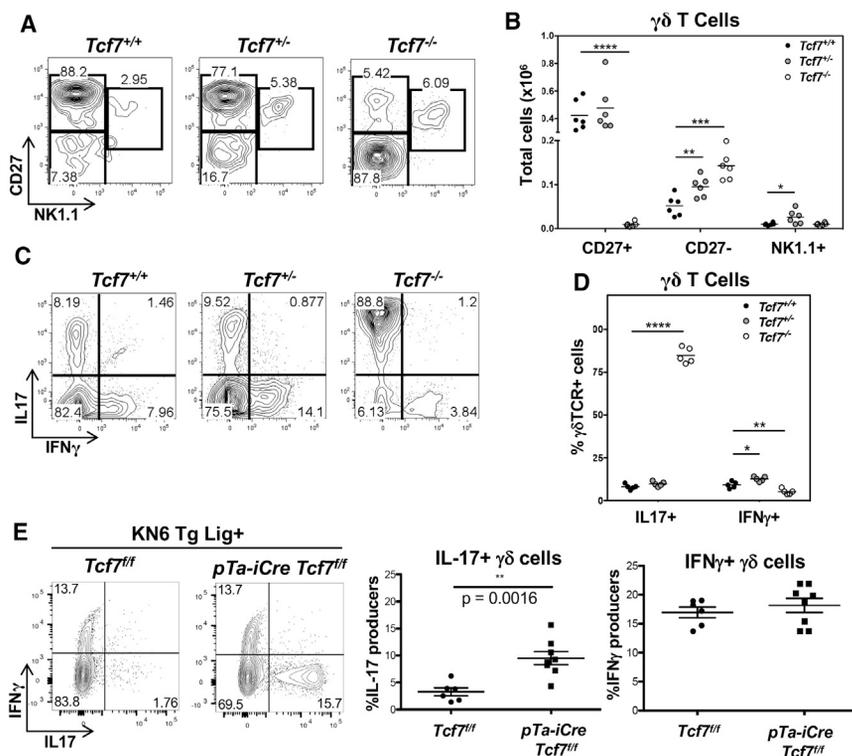

(A) KN6  $\gamma\delta$ TCR<sup>+</sup> *Rag2*<sup>-/-</sup> fetal liver progenitors were transduced with MLS and MLS-sh*Tcf7* and cultured for 5 days on OP9-DL1 monolayers lacking the KN6 TCR ligand (Lig-), in the presence of IL-7 and Flt3L. Electronically gated Thy1<sup>+</sup> GFP<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> cells, stained as indicated, are depicted (left panels). Graphs represent the proportion of CD4<sup>-</sup> CD8<sup>-</sup> CD24<sup>+</sup> CD73<sup>+</sup> ( $\gamma\delta$ Com.) and CD4<sup>-</sup> CD8<sup>-</sup> CD24<sup>-</sup> CD73<sup>+</sup> ( $\gamma\delta$  Mat.) cells within the Thy1<sup>+</sup> population. Data are representative of three independent experiments. p values were calculated for duplicate measurements within each experiment. Error bars represent  $\pm$  SD. \*p < 0.01; \*\*p < 0.005. (B and C) Thymocytes from *pTa-iCre Tcf7*<sup>+/+</sup> LSL-ZsG<sup>+</sup> and *pTa-iCre Tcf7*<sup>fl/fl</sup> LSL-ZsG<sup>+</sup> mice were stained as described above, and electronically gated ZsG<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> (B) or ZsG<sup>+</sup> (C) cells are displayed. Scatterplots representing the absolute number of  $\alpha\beta$  lineage CD4<sup>+</sup>CD8<sup>+</sup> (DP), CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> (Total  $\gamma\delta$ ), CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> CD24<sup>+</sup> CD73<sup>+</sup> ( $\gamma\delta$  Com.), CD4<sup>-</sup> CD8<sup>-</sup> CD24<sup>-</sup> CD73<sup>+</sup> ( $\gamma\delta$  Mat.) cells within the Thy1<sup>+</sup> population were calculated based on gate frequencies. IL-17 production (Figures 4A and 4B). Indeed, TCF1 deficiency caused a striking increase in IL-17-producing  $\gamma\delta$  T cells (Figures 4C and 4D), which was recapitulated by conditional ablation of *Tcf7* in hematopoietic cells, indicating that the effect is cell autonomous (Figures S5A and S5B). Importantly, the increase in IL-17 producers occurred regardless of V $\gamma$  usage, since, in addition to being observed among the V $\gamma$ 2 subset—which exhibits a modest IL-17 bias in normal mice—it was also observed in the V $\gamma$ 1 and V $\gamma$ 3 subsets, which typically exhibit an IFN- $\gamma$  bias (Figures S5C and S5D). Moreover, TCF1 deficiency was capable of markedly enhancing the generation of IL-17-producing  $\gamma\delta$  T cells in the KN6  $\gamma\delta$ TCR Tg model, where ligand-engagement normally favors adoption of the IFN- $\gamma$ -producing effector fate (Figure 4E) (Fahl et al., 2018). It should be noted that pTa-iCre-mediated ablation

development of other effector fates, but its capacity to do so is limited by developmental context.

The function of TCF1 in regulating the generation of IL-17-producing  $\gamma\delta$  T cells was previously suggested to be mediated by Wnt signaling through the activation of the  $\beta/\gamma$ -catenin cofactors (Malhotra et al., 2013). To assess the role of  $\beta/\gamma$ -catenin function in regulating  $\gamma\delta$  T cell development and effector fate, we examined  $\gamma\delta$  T cell development in *Tcf7* mutant mice (*p45*<sup>-/-</sup>) lacking the  $\beta/\gamma$ -catenin interacting domain (Xu et al., 2017). Interestingly, the *p45*<sup>-/-</sup> mutant mice did not display the profound alternations in  $\gamma\delta$  T cell development observed in TCF1-deficient mice (Figure 5), suggesting that  $\beta/\gamma$ -catenin interaction by TCF1—and, by extension, Wnt signaling—is not absolutely essential. However, the *p45*<sup>-/-</sup> mutant mice did exhibit a 2-fold reduction in  $\gamma\delta$

**Figure 4. TCF1 deficiency alters  $\gamma\delta$  T cell effector function**

(A) Thymocytes from *Tcf7*<sup>+/+</sup>, *Tcf7*<sup>+/-</sup>, and *Tcf7*<sup>-/-</sup> mice were analyzed for surface expression of Thy1, CD4, CD8, TCR $\delta$ , CD27, and NK1.1. Flow plots are pre-gated on Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> cells.

(B) Absolute numbers of Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> CD27<sup>+</sup> NK1.1<sup>-</sup>, Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> CD27<sup>-</sup> NK1.1<sup>+</sup>  $\gamma\delta$  T cells in the thymus of *Tcf7*<sup>+/+</sup>, *Tcf7*<sup>+/-</sup>, and *Tcf7*<sup>-/-</sup> mice were derived from gate frequencies and are represented as a scatterplot. (C and D) Thymocytes from *Tcf7*<sup>+/+</sup>, *Tcf7*<sup>+/-</sup>, and *Tcf7*<sup>-/-</sup> mice were depleted of CD4<sup>+</sup> and CD8<sup>+</sup> cells and stimulated with PMA and ionomycin at 37°C for 4 h. Cells were analyzed by intracellular staining for expression of IL-17 and IFN $\gamma$ . Flow plots were pre-gated on CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> cells. The frequency of cytokine-producing cells was derived from gate frequencies and is represented as a scatterplot.

(E) Thymocytes from KN6 Tg ligand-expressing (Lig<sup>+</sup>) mice were crossed to *pTa-iCre Tcf7*<sup>fl/fl</sup> mice, stimulated by PMA and ionomycin, and analyzed for cytokine production as in (C) and (D).

n = 6 mice (A and B), 5 mice (C and D), or 6 mice (E) per genotype. Each point represents an individual mouse. \*p < 0.05; \*\*p < 0.01; \*\*\*p < 0.001; \*\*\*\*p < 0.0001.

T cell numbers and an increase in the representation and number of mature  $\gamma\delta$  T cells (Figures 5A and 5B). There was also an increase in IL-17-producing  $\gamma\delta$  T cells (Figures 5C–5F). V $\gamma$  usage was altered in that the V $\gamma$ 1 subset was increased while the V $\gamma$ 2 subset was decreased, as was observed in the TCF1-deficient mice (Figure S6A); however, V $\gamma$ 3<sup>+</sup> cells were not observed in the thymus (Figure S6A). Finally, analysis of competitive reconstitution of  $\gamma\delta$  T cell development by  $\beta/\gamma$ -catenin double-deficient mice revealed no gross alterations in  $\gamma\delta$  T cells (Figure S6B). While our analysis of the p45 mutant mice suggests that the  $\beta/\gamma$ -catenin interacting domain of TCF1 may play some role in  $\gamma\delta$  T cell development, the expression level of the p45 TCF1 isoform is reduced (Xu et al., 2017), raising the possibility that the observed effects are due to reduced protein levels and not the loss of the  $\beta/\gamma$ -catenin binding capacity of TCF1 (Xu et al., 2017).

### E protein binding regulates *Tcf7* expression

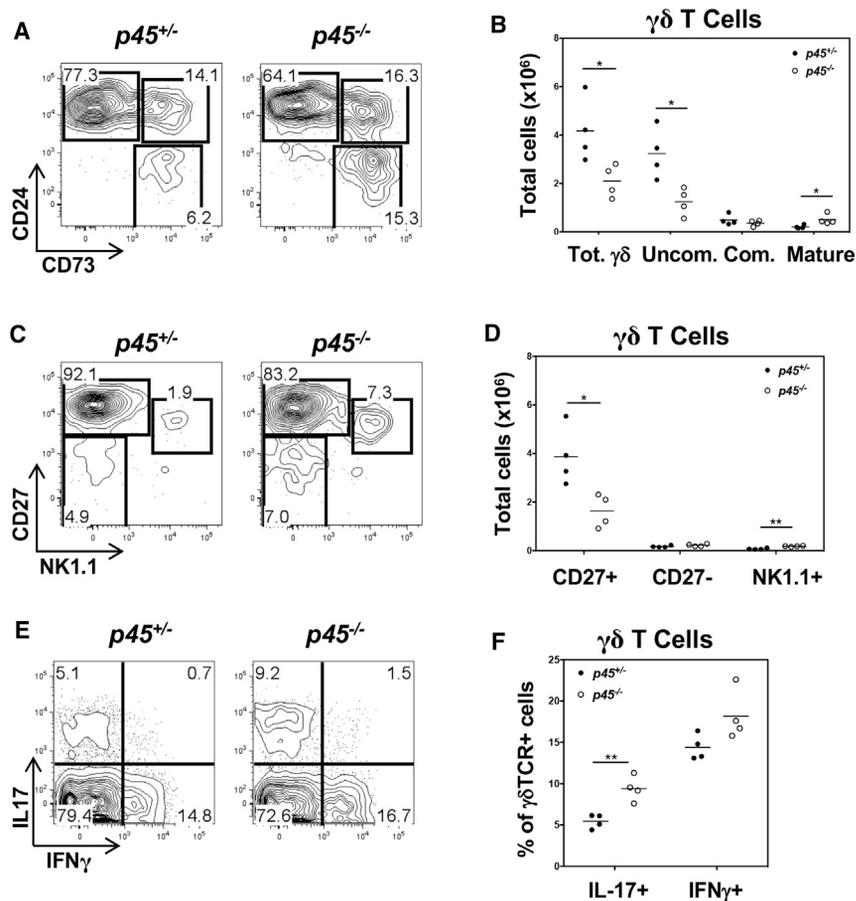

Collectively, our data indicate that the decline in *Tcf7* expression during  $\gamma\delta$  development plays an important role in  $\gamma\delta$  T lineage commitment and specification of effector fate. Because the suppression of E-box DNA binding protein activity by TCR signaling has been demonstrated to play an important role in  $\gamma\delta$  T cell lineage commitment and maturation (Lauritsen et al., 2009; Ueda-Hayakawa et al., 2009; Vervokakis et al., 2010), we wished to determine whether the repression of E protein activity was responsible for the decline in *Tcf7* expression. To investigate this possibility, we performed chromatin immunoprecipitation sequencing (ChIP-seq) analysis to identify the genomic sites of E protein binding. This analysis revealed an element in intron 1 (EPE) of the *Tcf7* locus in that is bound by both E2A and HEB in DN3 thymocytes (Figure 6A). Importantly, that binding was

lost, as progenitors express the  $\gamma\delta$ TCR (CD73<sup>-</sup>) and commit to the  $\gamma\delta$  fate (CD73<sup>+</sup>) (Figure 6A). Moreover, the repression of E protein function in TCR-deficient *Rag2*<sup>-/-</sup> fetal precursors by the E protein antagonist Id3 was sufficient to both repress E protein binding and *Tcf7* expression (Figures 6B and 6C).

To determine whether the EPE plays an important role in the regulation of *Tcf7* expression and  $\gamma\delta$  T cell development, we used CRISPR-based mutagenesis to delete a 500-bp fragment encompassing the E protein sites in intron 1 (EPE; Figure 7A). Importantly, ablation of the EPE fragment reduced TCF1 expression in developing  $\gamma\delta$ , but not  $\alpha\beta$ , lineage progenitors (Figures 7B and S7A). EPE ablation did not affect mouse viability, thymic cellularity, or  $\alpha\beta$  T cell development (Figure S7B); however, the ablation of EPE did alter  $\gamma\delta$  T cell development. Indeed, ablation of the EPE increased the proportion and number of mature  $\gamma\delta$  T cells and skewed their effector function, as it increased the proportion and number of IL-17-producing  $\gamma\delta$  T cells (Figure 7C). The skewing toward IL-17 production was associated with an increase in the proportion and number of CD27<sup>-</sup>  $\gamma\delta$  T cells (Figure S7C). The number of IFN- $\gamma$ -producing  $\gamma\delta$  T cells was not altered in  $\Delta$ EPE mice (Figure S7C). The effect on  $\gamma\delta$  T cell development and specification of effector fate was cell autonomous, as it was recapitulated in fetal liver chimeras (Figure S7D). Together, these observations link the decline in *Tcf7* expression that accompanies  $\gamma\delta$  T cell commitment and maturation to a critical regulatory EPE in the *Tcf7* locus (Figure 7D).

### DISCUSSION

TCF1 had previously been shown to play a critical role in Notch-mediated specification of the T cell fate in the thymus (Germar

**Figure 5. The catenin-interacting domain of TCF1 is not essential to support  $\gamma\delta$  T cell development and function**

(A) Thymocytes from *p45<sup>+/-</sup>* and *p45<sup>-/-</sup>* mice were analyzed for surface expression of Thy1, CD4, CD8, TCR $\delta$ , CD24, and CD73. Flow plots are pre-gated on Thy1<sup>+</sup> CD4<sup>-</sup> CD8<sup>-</sup> TCR $\delta$ <sup>+</sup> cells.

et al., 2011; Weber et al., 2011). Moreover, TCF1 plays a critical role in supporting  $\alpha\beta$  T cell development, which is severely attenuated by TCF1 deficiency (Goux et al., 2005; Okamura et al., 1998); however, the role of TCF1 in  $\gamma\delta$  T cell development is much less well understood. We report here that although TCF1 expression is maintained in developing  $\alpha\beta$  T cells, TCF1 significantly declines as T cell progenitors commit to the  $\gamma\delta$  fate and mature. The decline in TCF1 expression influences both  $\gamma\delta$  lineage commitment and effector fate. Indeed, genetic attenuation of TCF1 expression promotes adoption of the  $\gamma\delta$  fate and maturation of  $\gamma\delta$  T cells. We note that this occurs even in response to suboptimal  $\gamma\delta$ TCR signals. TCF1 deficiency also radically alters  $\gamma\delta$  effector fate, converting essentially all  $\gamma\delta$  cells into IL-17-producing effectors, regardless of V $\gamma$  gene usage; however, this is somewhat mitigated after the receipt of strong TCR signals that usually promote IFN- $\gamma$  production and when TCF1 loss is induced later in development (Sumaria et al., 2017). These findings indicate that the capacity of TCF1 loss to promote the IL-17-producing effector fate, even in the context of strong TCR signals, is more constrained in cells that have developed beyond the DN1d stage, a subpopulation of cells with increased IL-17 precursor potential (Spidale et al., 2018). Finally, we have identified a novel E-protein-bound regulatory element that selectively controls TCF1 expression in  $\gamma\delta$ , but not  $\alpha\beta$ , T cell progen-

itors. Specifically, we determined that TCF1 expression declines during  $\gamma\delta$  development, because of the suppression of E protein activity, presumably in response to TCR-induced expression of the Id family of E protein antagonists, and this is regulated by the EPE in the first intron of the *Tcf7* locus.

It is well established that TCF1 expression is induced by Notch signaling in T cell precursors and plays a critical role as a molecular effector of Notch-mediated orchestration of T lineage commitment (Mercer et al., 2011; Weber et al., 2011). We find that the elevated levels of TCF1 are maintained during the development of  $\alpha\beta$  T cells, consistent with the marked impairment of  $\alpha\beta$  T cell development caused by TCF1 deficiency (Okamura et al., 1998; Verbeek et al., 1995). By contrast, we found that expression of TCF1 declines during  $\gamma\delta$  commitment.  $\gamma\delta$  T cell development is less dependent upon Notch signaling (Ciofani et al., 2006), and Notch expression is reduced during  $\gamma\delta$  T cell development (Lauritsen et al., 2009). Consequently, it was possible that the attenuation of Notch expression was contributing to the decrease in TCF1 expression observed in developing  $\gamma\delta$  cells. Importantly, we have previously demonstrated that the Notch independence of  $\gamma\delta$  T cell development is dependent upon the induction of the E protein antagonist Id3 by strong/prolonged signals transduced by the  $\gamma\delta$ TCR (Lauritsen et al., 2009). This suggested that Id3-dependent antagonism of E protein function might be important in regulating

**Figure 6. TCF1 expression is regulated by E proteins in response to  $\gamma\delta$ TCR signaling**

(A) ChIP-seq analysis of E2A and HEB binding within the *Tcf7* locus in fetal liver progenitor-derived *Rag2*<sup>-/-</sup> DN3 cells and KN6  $\gamma\delta$ TCR-transduced *Rag2*<sup>-/-</sup> CD24<sup>+</sup> CD73<sup>-</sup> and CD24<sup>+</sup> CD73<sup>+</sup> cells. Data are representative of two independent experiments.

(B) ChIP-qPCR of E2A and HEB binding within the *Tcf7* and *Gapdh* loci was performed on fetal liver progenitor-derived *Rag2*<sup>-/-</sup> DN3 cells transduced with MIY or MIY-Id3 and cultured on OP9-DL1 monolayers in the presence of IL-7 and Flt3L at 37°C for 3 days.

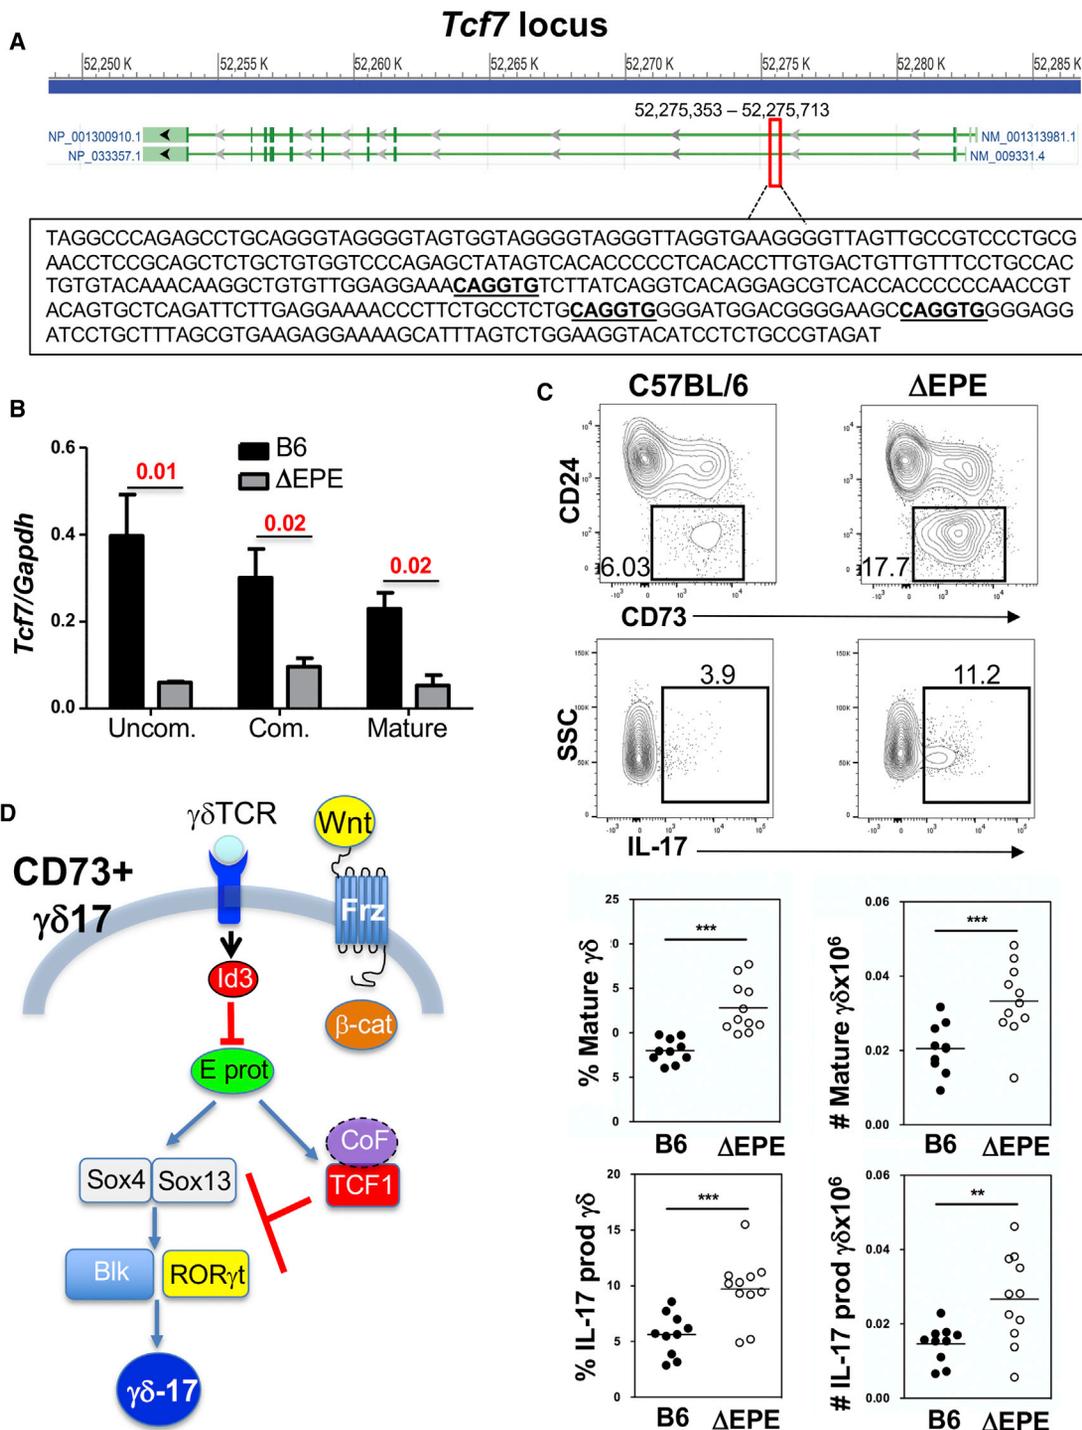

(C) Quantitative real-time PCR analysis for *Tcf7* mRNA was performed on the samples in (B). mRNA levels were normalized to the expression of *Gapdh*. Data are representative of three independent experiments. Error bars represent  $\pm$  SD of triplicate measurements within each experiment.

TCF1 expression during  $\gamma\delta$  T cell development. Indeed, we detected E protein binding to a cluster of E protein binding sites in the first intron of the *Tcf7* locus and determined that binding by E2A and HEB declined during  $\gamma\delta$  lineage commitment. E2A binding to this site has also been observed in naive CD8 T cells (Masson et al., 2013). Importantly, genetic ablation of the regulatory EPE containing this cluster of E protein binding sites was sufficient to phenocopy some of the developmental alterations caused by TCF1 deficiency. Specifically, ablation of this element caused a cell-autonomous increase in the generation of mature  $\gamma\delta$  cells and skewed them to the IL-17-producing effector fate, albeit to a lesser extent than was observed in TCF1-deficient mice. It is worth noting that we also observed additional E2A/HEB binding peaks 5' to the *Tcf7* locus that are also lost during  $\gamma\delta$  T cell development (data not shown). This suggests either that these E-protein-bound elements do not play a critical role in maintaining TCF1 expression in developing  $\gamma\delta$  T cells or that loss of the EPE disables the capacity of E proteins to regulate TCF1 expression through those other elements. A recent report revealed that an element nearby one of those E protein peaks plays an important role in supporting TCF1 expression in developing  $\alpha\beta$  lineage progenitors and innate lymphoid cells (Harly et al., 2020), raising the possibility that different elements are used to support TCF1 expression in different cell types.

Although the decline in TCF1 expression that accompanies  $\gamma\delta$  T cell development plays an important role in separation of the  $\alpha\beta$  and  $\gamma\delta$  T cell lineages, the basis by which TCF1 does so remains unclear. TCF1 has recently been shown to be capable of initiating the epigenetic identity of T cells (Johnson et al., 2018). Moreover, TCF1 function is known to be regulated by Wnt signaling through association with  $\beta$ -catenin (Staal and Sen, 2008), and its loss in

the thymus has previously been linked to skewing of  $\gamma\delta$  function to the IL-17-producing effector fate (Malhotra et al., 2013), implicating Wnt signaling as an important environmental cue that influences  $\gamma\delta$  fate and function. Consistent with this notion, mutant mice in which TCF1 lacks the  $\beta$ -catenin-interacting domain did manifest some of the developmental anomalies associated with TCF1 deficiency, including enhanced  $\gamma\delta$  maturation and IL-17 production. However, because the p45 mutant TCF1 isoform that cannot bind  $\beta/\gamma$ -catenin is expressed at reduced levels, the alterations in  $\gamma\delta$  T cell development observed in these mice may result from reduced expression rather than the inability to bind catenins (Xu et al., 2017). This would be consistent with the absence of obvious alterations in  $\gamma\delta$  T cell development in mice doubly deficient for  $\beta$ - and  $\gamma$ -catenin. Taken together, these data suggest that Wnt signaling is unlikely to play a significant role in modulating TCF1 function in developing T cells. Nevertheless, it remains possible that, if the catenin binding domain of TCF1 does play a role, it probably does so through interaction with a distinct partner that influences TCF1 function in developing T cells, as a number of other potential partners have been identified (Figure 7D) (Steinke et al., 2014).

It is well established that commitment of bipotent DN T cell progenitors to the  $\alpha\beta$  or  $\gamma\delta$  fate is predominantly determined by the nature of the TCR signals transduced, with weak and strong signals favoring the  $\alpha\beta$  and  $\gamma\delta$  fates, respectively (Haks et al., 2005; Hayes et al., 2005). We found that TCF1 loss facilitated the adoption of the  $\gamma\delta$  fate, even in response to severely attenuated TCR signals. Consequently, it is likely that declining TCF1 expression during  $\gamma\delta$  development influences  $\gamma\delta$  fate specification by modulating either the nature of the TCR signal or its effect on gene expression. Although TCF1 has not been implicated in the regulation of TCR signaling itself, it has been implicated in regulating the expression of genes that are selectively required for the development of  $\alpha\beta$  lineage cells (Mercer et al., 2011; Weber et al., 2011). In particular, *Bcl11b* is a TCF1 target whose expression is markedly

**Figure 7. Ablation of an E-protein-binding regulatory element in the *Tcf7* locus diminishes *Tcf7* expression and alters  $\gamma\delta$  T cell development**

(A) Schematic of E protein binding sites within the regulatory E-protein-bound element (EPE) in the *Tcf7* locus. E box sites are underlined.

(B) Quantitative real-time PCR analysis for *Tcf7* mRNA in electronically sorted  $\text{Thy1}^+ \text{CD4}^- \text{CD8}^- \text{TCR}\delta^+ \text{CD24}^+ \text{CD73}^-$  (Uncom.),  $\text{CD24}^+ \text{CD73}^+$  (Com.), and  $\text{CD24}^- \text{CD73}^+$  (Mat.)  $\gamma\delta$  T cell subsets from C57BL/6 and  $\Delta\text{EPE}$  mice. mRNA levels were normalized to *Gapdh*. Data are representative of 3 independent experiments. Error bars represent  $\pm$  SD of triplicate measurements within each experiment.

(C) Top panel: thymocytes from C57BL/6 and  $\Delta\text{EPE}$  mice were analyzed for surface expression of *Thy1*, *CD4*, *CD8*, *TCR}\delta*, *CD24*, and *CD73*. Flow plots are pre-gated on  $\text{Thy1}^+ \text{CD4}^- \text{CD8}^- \text{TCR}\delta^+$  cells. Bottom panel: thymocytes from C57BL/6 and  $\Delta\text{EPE}$  mice were depleted of  $\text{CD4}^+$  and  $\text{CD8}^+$  cells and stimulated with PMA and ionomycin at  $37^\circ\text{C}$  for 4 h. Cells were analyzed for cytokine production by intracellular staining for IL-17. Flow plots are pre-gated on  $\text{CD4}^- \text{CD8}^- \text{TCR}\delta^+$

(legend continued on next page)

diminished during  $\gamma\delta$  development and whose function is predominantly required for  $\alpha\beta$  T cell development, since Bcl11b deficiency markedly attenuates  $\alpha\beta$  T cell development but is dispensable for most  $\gamma\delta$  T cells (Ikawa et al., 2010; Li et al., 2010a, 2010b). The loss of BCL11B and other TCF1 targets during  $\gamma\delta$  development presumably contributes to the loss of  $\alpha\beta$  fate potential by CD73<sup>+</sup>  $\gamma\delta$  lineage cells (Coffey et al., 2014). Nevertheless, the loss of  $\alpha\beta$  fate potential alone does not explain the capacity of progenitors to adopt the  $\gamma\delta$  fate in response to suboptimal TCR signals and suggests that the remodeling of expression of other TCF1 targets also decreases the threshold to adoption of the  $\gamma\delta$  fate. The TCF1 targets responsible for this change in threshold remain to be identified.

Finally, we also contend that our findings provide a potential explanation for the observation that the development of CD73<sup>+</sup> IL-17-producing  $\gamma\delta$  T cells does not depend upon the E protein HEB, which supports expression of critical IL-17-promoting targets Sox4, Sox13, and ROR $\gamma$ t (Malhotra et al., 2013; Wencker et al., 2014; In et al., 2017) (Figure 7D). Indeed, TCF1 has been demonstrated to be an antagonist of the HMG box family members Sox4 and Sox13, which promote the IL-17-producing  $\gamma\delta$  effector fate (Malhotra et al., 2013). Consequently, we advance a model in which the strong TCR signals that promote adoption of CD73<sup>+</sup> IL-17-producing  $\gamma\delta$  T cells do so by limiting the capacity of TCF1 to antagonize Sox4 and Sox13 function. This is mediated by blocking E protein binding to the *Tcf7* locus and reducing TCF1 expression. The reduced level of TCF1 is sub-stoichiometric to that required to antagonize the capacity of even the lower levels of Sox4 and Sox13 to promote adoption of CD73<sup>+</sup> IL-17-producing  $\gamma\delta$  T cells.

In summary, our study reveals a critical role for the expression level of TCF1 in influencing the  $\alpha\beta$  versus  $\gamma\delta$  lineage choice by T lineage progenitors in the thymus. Moreover, we reveal new insights into how TCF1 expression and function are controlled. Although the function of TCF1 is most often regulated by Wnt activation of  $\beta$ -catenin (Staal and Sen, 2008), this axis is dispensable in developing  $\gamma\delta$  T cells. Furthermore, we have determined that TCF1 levels at this lineage branch point do not appear to be controlled by Notch, as is the case at earlier developmental stages, but instead are controlled by E protein binding and depend on a regulatory element within the first intron of the *Tcf7* locus. This suggests that TCF1 expression in  $\gamma\delta$  T cell progenitors is modulated by TCR-mediated induction of E protein antagonists, including Id3. This mode of regulation may be restricted to developing  $\gamma\delta$  T cell progenitors, since a distinct element appears to be utilized to support TCF1 expression in developing  $\alpha\beta$  and innate lymphoid cells (Harly et al., 2020). It is also possible that this mode of regulation is important in other contexts, including the generation of memory CD8 T cells, where several E-protein-bound elements have been reported near the *Tcf7* locus (Masson et al., 2013; Miyazaki et al., 2017). Together, our findings link TCR signaling, the E-Id axis, and TCF1 in a common framework

that underpins the specification and developmental progression of the  $\gamma\delta$  T cell lineage.

## STAR★METHODS

Detailed methods are provided in the online version of this paper and include the following:

- KEY RESOURCES TABLE
- RESOURCE AVAILABILITY
  - Lead contact
  - Materials availability
  - Data and code availability
- EXPERIMENTAL MODEL AND SUBJECT DETAILS
  - Animals
  - Generation of mutant mice with CRISPR-Cas9 system
- METHOD DETAILS
  - Flow cytometry and proliferation analysis
  - Retroviral transduction and OP9-DL1 cultures
  - ChIP-qPCR, ChIP-seq, and RNA-seq analysis
  - Q-PCR and immunoblotting
  - Fetal liver chimeras
- QUANTIFICATION AND STATISTICAL ANALYSIS

**RESOURCE AVAILABILITY**

**Lead contact**

Further information and requests for resources and reagents should be directed to and will be fulfilled by the Lead Contact, David Wiest ([David.Wiest@FCCC.edu](mailto:David.Wiest@FCCC.edu))

**Materials availability**

All reagents and novel mouse strains used in this study are available upon request from the Lead Contact, David Wiest.

**Data and code availability**

The accession number for the ChIP-Seq and RNA-Seq data reported in this study is GEO: GSE162292.

**EXPERIMENTAL MODEL AND SUBJECT DETAILS**

**Animals**

All mice were maintained in AALAC-accredited laboratory animal facilities at Fox Chase Cancer Center, National Institute of Aging, National Cancer Institute, or the University of Iowa. All experiments were conducted under approved institutional animal care and use committee (IACUC) approved protocols on both male and female age and sex matched mice 6-8 weeks of age. KN6 Tg mice, Ptcr*a*-iCre Tg, *Tcf7*<sup>-/-</sup>, *Tcf7*<sup>GFP</sup>, *Tcf7*<sup>fl/fl</sup> and *p45*<sup>-/-</sup> mice were previously described (Abbas et al., 1991; Haks et al., 2005; Luche et al., 2013; Steinke et al., 2014; Verbeek et al., 1995; Xu et al., 2017; Yang et al., 2015).

**Generation of mutant mice with CRISPR-Cas9 system**

EPE Mutant mice were generated as previously described (Wang et al., 2013). Oligos were ordered from Integrated DNA Technologies and the gRNA sequences used were: TCF-EPE gRNA1- ATAAGTCCGAGGTTAGATT and TCF-EPE gRNA2- AAGCAGCGTATCTACGGCAG. gRNA were synthesized *in vitro* with HiScribe T7 High Yield RNA Synthesis Kit (New England Biolabs, #E2040S), and purified with RNA Clean & Concentrator (Zymo Research, #R1015) according to manufacturer's protocol. Cas9 protein (PNA Bio, #CP03) 30 ng/ $\mu$ l, two gRNAs each 0.3  $\mu$ M were mixed according to PNA Bio protocol. 10  $\mu$ l of the mixture was micro-injected into each embryonic zygote. Genomic DNA was isolated from transgenic mice tail with DNeasy Blood & Tissue Kits (QIAGEN, #69506) and used for genotyping using the following oligos: TCF-EPE F - AGTCACAGGAGGGCGTACGG and TCF-EPE R - GCAGCCTGTCCTAGTCCCAGG. Purified PCR products were further cloned into pGEM<sup>®</sup>-T Vector Systems (Promega, #A3600), transformed into DH5 $\alpha$  competent cells (Thermo Fisher Scientific, #18258012), and sequenced by GENEWIZ.

**METHOD DETAILS**

**Flow cytometry and proliferation analysis**

Flow cytometry was performed on single cell suspensions from thymus and epidermis. Cells were isolated and stained with the following antibodies: anti-CD4 (GK1.5), anti-CD8 (53-6.7), anti-CD24 (M1/69), anti-CD25 (PC61), anti-CD27 (LG.3A10), anti-CD44 (IM7), anti-CD73 (TY/11.8), anti-CD127 (A7R34) anti-NK1.1 (PK136), anti-Thy1.2 (53-2.1), anti-TCR $\delta$  (GL3), anti-V $\gamma$ 1 (2.11), anti-V $\gamma$ 2 (UC3-10A6), anti-V $\gamma$ 3 (536), anti-IL17A (TC11-18H10.1) and anti-IFN $\gamma$  (XMG1.2). The antibodies were purchased from eBioscience or BioLegend. Intracellular flow cytometry for cytokine production was performed as previously described (Coffey et al., 2014). Intracellular staining TCF1 was performed on thymocytes first stained with antibodies to the indicated cell surface proteins, fixed with BD Fixation/Permeabilization Solution for 20min at 4°C, washed with BD Perm/Wash Buffer, and then stained internally with anti-TCF1 (AF647-TCF1, R&D Systems) for 40 min at 4°C. Analysis of proliferation was performed using the Click-iT Plus EdU assay (Invitrogen) according to manufacturer's specifications. Briefly, thymocytes were incubated with 10  $\mu$ M EdU for 2 hours,

washed with 1% BSA/PBS, and stained with the indicated fluorochrome-coupled antibodies. Following fixation with 4% paraformaldehyde for 15 min, the cells were incubated with Pacific Blue picolyl azide for 30 min at room temperature to visualize incorporated EdU. Multi-parametric flow cytometric analysis was performed on all samples using an LSRII flow cytometer (BD Biosciences) with FACSDiva software. Dead cells were excluded from analyses of unfixed populations using propidium iodide (PI). Data were analyzed using FlowJo software. Cell populations to be purified by flow cytometry were isolated using a FACS Aria Cell Sorter (BD Biosciences).

### Retroviral transduction and OP9-DL1 cultures

Retroviral particles were produced by transient calcium phosphate transfection of Phoenix cells. pMiG and pMiG-IId3 vectors have been previously described (Lauritsen et al., 2009; Xing et al., 2016). shRNAs targeting *Tcf7* were expressed in the MSCV-based vector MLS (Dickins et al., 2005). OP9-DL1 cocultures were performed as previously described (Coffey et al., 2014). Fetal livers were harvested from KN6  $\gamma\delta$ TCR+ *Rag2*<sup>-/-</sup> mice at day 14.5 of gestation and cell suspensions were centrifuged over a cushion of Lympholyte-M (Cederlane Labs). Isolated cells were expanded on OP9-DL1 cells for 4 days in the presence of 5 ng/ml IL-7 and 5 ng/ml Flt3L (R&D Systems). At day 4 of culture, cells were transduced by spin infection using retroviral supernatant treated with 8  $\mu$ g/ml polybrene (Sigma-Aldrich). Infected cells were cultured overnight, and GFP+ DN3 (Thy1.2+ CD4- CD8- CD25+ CD44-) cells were electronically sorted and cultured for 5 days on OP9-DL1 Ligand- monolayers (Coffey et al., 2014). At day 5 of culture, cells were harvested and analyzed by flow cytometry. *In vitro* cytokine stimulation with IL1 $\beta$  and IL23 was performed as previously described (Wencker et al., 2014).

### ChIP-qPCR, ChIP-seq, and RNA-seq analysis

*Rag2*<sup>-/-</sup> DN3 cells were derived from fetal liver progenitors cultured on OP9-DL1 monolayers as previously described (Coffey et al., 2014). To generate  $\gamma\delta$ TCR+ CD24+ CD73- and  $\gamma\delta$ TCR+ CD24+ CD73+ cells, *Rag2*<sup>-/-</sup> fetal liver progenitors were cultured on OP9-DL1 monolayers for 7 days in the presence of 5 ng/ml IL7 and 5 ng/ml Flt3L (R&D Systems). At day 7 of culture, *Rag2*<sup>-/-</sup> DN3 cells were harvested and cultured overnight on MIY-KN6  $\gamma\delta$ TCR-producing GP+E cells in the presence of 5 ng/ml IL7, 5 ng/ml Flt3L, and 8  $\mu$ g/ml polybrene (Sigma Aldrich). YFP+ DN3 (Thy1.2+ CD4- CD8- CD25+ CD44-) cells were electronically sorted and cultured for 3 days on OP9-DL1 monolayers. At day 3 of culture, cells were harvested and fixed for 10 minutes at 20°C with 1% (wt/vol) formaldehyde, following which the Thy1+ YFP+ CD4- CD8- CD24+ CD73- and Thy1+ YFP+ CD4- CD8- CD24+ CD73+ subsets were purified by flow cytometry. Chromatin immunoprecipitation was performed as previously described (In et al., 2017; Miyazaki et al., 2011). Cells were lysed and sonicated, and sonicated chromatin was immunoprecipitated with 10  $\mu$ g anti-E2A (affinity-purified rabbit polyclonal sera raised against the last 12 amino acids of the C terminus of E2A) or 10  $\mu$ g anti-HEB (affinity-purified rabbit polyclonal sera raised against the last 12 amino acids of the C terminus of HEB). Samples were washed and bound chromatin was eluted. Cross-linking was reversed overnight at 65°C. Samples were treated with RNase A and proteinase K, and DNA was purified using the ChIP DNA Clean and Concentrator Kit (Zymo). For ChIP-qPCR, quantitative real time PCR was performed with QuantiTect SYBR Green PCR Kit (QIAGEN) on an ABI Prism 7700 Real-Time PCR machine (Applied Biosystems). Primer sequences were as follows: *Tcf7* (TGACGCTCCTGTGACCTGAT, AGTCACACCCCTCACACCT), *Gapdh* (TGGCGTAGCAATCTCCTTTT, CTCCTGGCTTCTG TCTTTGG). For ChIP-Seq, purified DNA was ligated to an adaptor, amplified by PCR (Illumina) and sequenced. 'Reads' were aligned to the mm10 assembly with Bowtie software for the alignment of short DNA sequences. Custom tracks generated by the UCSC Genome Browser were used for visualization. For RNA-Seq, DN3, Thy1+ YFP+ CD4- CD8- CD24+ CD73-, and Thy1+ YFP+ CD4- CD8- CD24+ CD73+ subsets were produced as above, isolated by flow cytometry and lysed in TRIzol (Invitrogen). Reads were aligned using STAR and analyzed using HOMER. E protein ChIP-Seq and RNA-Seq datasets have been deposited in GEO (GEO: GSE162292).

### Q-PCR and immunoblotting

RNA was purified using the RNeasy MiniPrep Kit (QIAGEN) per manufacturer's instructions and converted to cDNA using the SuperScript II kit (Invitrogen) with oligo dT<sub>(12-18)</sub> primers (Invitrogen). Expression of indicated genes was measured by real time PCR using stock TaqMan primer/probe sets on an ABI Prism 7700 Real Time PCR machine (Applied Biosystems). Analysis was performed in triplicate, normalized by *Gapdh*, and converted into fold difference. Primer and probes were from Applied Biosystems: *Gapdh*, Mm99999915\_g1; *Tcf7*, Mm00493445\_m1; *Ccr10*, Mm01292449\_m1. SCID.adh cells were transduced with MLS, MLS-sh*Tcf.7* #1, or MLS-sh *Tcf.7* #3 and lysed in RIPA Buffer (20 mM HEPES [pH 7], 150 mM NaCl, 1% deoxycholate, 1% Nonidet P-40, 0.1% SDS, 1 mM Na<sub>2</sub>VO<sub>4</sub>, 2 mM EDTA, and a complete protease inhibitor mixture; Roche). Samples were resolved on NuPage Novex Bis-Tris gels (Invitrogen) and blotted with the following antibodies: anti-TCF1 (C63D9, Cell Signaling) and anti-GAPDH (6C5, Millipore).

### Fetal liver chimeras

100,000 Fetal liver progenitors were transferred *i.v.* into each irradiated, allotype-marked (CD45.2) recipient. 6 weeks after engraftment, thymic explants were analyzed by flow cytometry to assess developmental progression and by intracellular staining to measure cytokine production, as described (Fahl et al., 2018).

#### QUANTIFICATION AND STATISTICAL ANALYSIS

Statistical significance of alterations in cell populations or changes in gene expression was assessed using the two-tailed Student t test. Details of all statistical analysis can be found in the legends of both the main and supplemental figures, including the statistical tests used, the exact value of n (number of mice, unless defined otherwise), and the definition of confidence intervals.
